#### CHAPTER III

#### METHODOLOGY

#### Population

The data for this study were collected in the schools of Karabuk, Turkey. There are 91 public schools in Karabuk that employ five or more full-time teachers. The 1946 teachers employed within these 91 schools were the target population for this study. Teachers in the schools serve 36,415 students. The province is divided into six townships (school districts), each has an appointed superintendent of public schools. A superintendent in a township reports to the superintendent of the province. The province superintendent reports to the governor and to the ministry of education at the capital city, Ankara. The ministry of education appoints teachers to the province. The superintendent of the province reports the vacancies in the province schools to the governor. The governor appoints teachers to schools based on the superintendent's report. Teachers in this population have tenure when they complete the first year of their service.

The province is settled in the valleys and plateaus formed by the Yenice river which is fed by the joining of Araç and So• anl• streams, in the north-west Black Sea region of Turkey. Approximately, 250,000 people live in the province. Upon the establishment of the steel plant in 1937, the province made its mark on the country's economy. The majority of community is composed of blue-collar workers. The province houses one of the biggest steel plants in the nation. The province is also known for its forests and the historical city of Safranbolu. An overwhelming majority of people migrated to the city from other parts of the country to work at the factory. Unfortunately, the province has been in a severe economic decline for ten years.

## **Data Collection**

Survey instruments and documentary sources were used in the data collection. Data were collected from teachers in 68 of 91 schools having more than 5 full-time teachers. Permission was granted from the governor's office to conduct the research in the province on June 23, 1998. A document showing names of schools in the province, locations of each school, total number of teachers in each school, number of students in each school, and total number of classrooms in

each school was provided by the central office. However, a list of the teachers, phone numbers of schools, and addresses of schools was not provided. Locating some of the schools posed quite a challenge. The central offices of the public instruction at the province send a memo to each school about the research. In the memo, the province superintendent asked the cooperation of school staff. Participation in the study was voluntary. Convenience sampling was used.

Instruments were distributed to teachers during school visitations. Three people distributed the instruments. First, schools in the province center and surrounding areas were visited because they were easy to locate. Then schools in remote locations were visited. Since there was no map to use, researchers had to ask people on the streets for directions to schools. Researchers depended heavily on public transportation to arrive at schools. There were times researchers had to walk more than an hour to reach schools in remote areas. Instruments were picked up at a designated time and date from each school. This was the first experience for almost all teachers who received the instruments to participate in a study.

Instruments were distributed to 725 teachers in 68 of 91 schools in Karabuk over the course of 20 days. The number of instruments returned was 512. Cases that had more than three missing responses for any scale were eliminated from the analysis. For the remaining cases, means were substituted for missing values. Twenty-six cases were eliminated from the data. The total number of cases was reduced from 512 to 486. This number (486) is 67% of the 725 teachers to whom survey instruments were distributed. These completed survey instruments were divided randomly into a pilot sample (N = 162) and a research sample (N = 324). The pilot sample was used for preliminary item analyses, and the research sample was used to answer the research questions using the instruments as revised during the pilot analyses. Although a convenience sampling was used, both pilot sample and the research sample mirror fairly well the population characteristics as shown in Table 3.

<u>Note</u>. \* The counts for the pilot and research sample often exceed the counts for the population because teachers from the same school were selected into the pilot and research samples.

### **Analysis**

# Analysis of Pilot sample Data

### Analysis of Items in Bureaucratic Dimensions

From the literature, items measuring Hall's six bureaucratic dimensions were extracted. Items from six researchers' instruments were selected. Items were categorized by dimensions, and items used by each researcher to measure a specific dimension of bureaucracy were identified. Table 4 displays the complete list of items included in the instruments, each identified by the author of item. The pool of items and the last names of researchers who used the item were provided in Table 4. If a researcher used an item, an "X" mark was placed in the cell associated with the name of the researcher and the item.

For each of the six researchers, responses of teachers to items identified under the same dimension by the particular researcher were added together and divided by the number of items used by the researcher to measure the dimension. This procedure generated six different scores for the same dimension, because there were six researchers. In other words, each of the six dimensions had six different scores because all of six researchers have attempted to measure all of Hall's six dimensions of bureaucracy. In addition to these six, a seventh score for each bureaucratic dimension was computed by averaging the responses to all items identified under the same dimension, regardless of authorship of items. In other words, every dimension had seven scores, one based on all items across all authors and a separate score for the items of each of the six authors.

Item/total score correlations were computed for each item using each of the seven scores as the criterion. This procedure generated seven correlation coefficients for an item in a dimension. If three or more of these seven correlation coefficients were higher than .35, the item was kept for further analyses. If not, the item was eliminated from further consideration.

Items surviving the procedure explained above were subjected to reliability analyses. A separate reliability analysis for items in each dimension was carried out. The "corrected item total correlation" and the "alpha if item deleted" statistics in the reliability analysis of SPSS program were examined for each item. If, for an item, the corrected item-total correlation was

negative or lower than .20 and the elimination of the item improved the alpha coefficient of the scale more than .02 points, the item was considered for elimination.

Items that survived the procedure explained above were subjected to a factor analysis with an oblique rotation using the oblimin procedure of the SPSS program. Items that had a factor loading lower than a .10 or evidenced factorial complexity were considered for elimination. If an item loaded highly on more than one factor, that item had a factorial complexity.

# Analysis of Items in Sense of Power Scale

From the literature, items measuring sense of power were extracted. The pool of items and the last names of researchers who used these items are provided in table 5. The table was organized dimension by dimension. If a researcher used an item, an "X" mark was placed in the cell associated with the name of the researcher and the item. Items were subjected to a reliability analysis. The "corrected item total correlation" and the "alpha if item deleted" statistics in the reliability analysis of SPSS program were examined for each item. If, for an item, the corrected item total correlation was negative or lower than .20 and the elimination of the item improved the alpha coefficient of the scale more than .02 points, the item was considered for elimination. Items surviving this procedure were subjected to a factor analysis with an oblique oblimin rotation using the SPSS program. Items that had a loading score lower than a .10 or those evidenced factorial complexities were considered for elimination.

#### Analysis of Research Sample Data

### Replication of the Factor Structure of Items using the Research Sample Data

The items that survive the item analyses conducted using the pilot data were subjected a factor analysis conducted using the research sample data. A principal axis factoring with an oblique oblimin rotation was used to extract factors. The factor structure resulting from the pilot sample data and in the research sample data were compared. Items that converged under the same factor in both analyses were judged to represent a dimension of bureaucracy. A score on each dimension was calculated for each respondent by adding the teacher's responses to items grouped under each factor. This score was divided by the number of items in the dimension. This

procedure yielded a score on each dimension for each teacher.

# Research Question I

After calculating a score for each respondent for each dimension identified in the principal axis factor analysis, the inter-correlations among dimension were calculated.

Intercorrelations among dimension scores were subjected a second order factor analysis with an oblique rotation. In addition to the factor structure of dimensions, a two dimensional scatter plot of loadings was examined to clarify clustering of dimensions. The "Y" axis was assigned the loading scores of all dimensions on the first factor. The "X" axis was assigned the loading scores of all dimensions on the second factor. Then, intercepts (coordinates) for each of the six dimension were marked. This plot provided a visual display for the locations of dimensions relative to each other in two-dimensional space. The closer the coordinates of dimensions, the higher the correlation among the dimensions. This plot also provided a visual inspection of groupings among dimensions. According to theory, dimensions were expected to group under two clusters. If the responses of teachers in this sample are similar to what has been reported for teachers in the U.S. and Canada, bureaucratic dimensions are expected to create two higher order dimensions. These two higher-order dimensions were named control and expertise.

Bureaucratic dimension scores within each cluster were averaged to arrive at a single measure of each higher-order dimension for each respondent. Scores on these higher order factors were next subjected to a k-mean cluster analysis using SPSS. The purpose of this analysis was to identify relatively homogeneous groups of teachers based on their scores on the higher-order dimensions (control & expertise). K-mean cluster procedure is used when there is a theory concerning the number of clusters regarding cases or variables. The literature implies four distinct bureaucratic clusters: Weberian, authoritarian, collegial, and chaotic. The program was forced to create exactly 4 clusters that were to be as distinct as possible. The procedure is similar to analysis of variance in which the program minimizes the variability within clusters and maximizes the variability between clusters.

The procedure provided means for each cluster on both control and expertise higher-order dimensions. Each cluster had a mean score for control and a mean score for expertise. The mean score of control for a cluster, for example, was calculated by averaging the control higher-order

dimension scores of all teachers within the cluster. If a cluster's mean score was *high* on control relative to other clusters' means scores on control and if the cluster's mean score was *high* on the expertise relative to other clusters' mean scores on expertise, this cluster was named Weberian. If a cluster's mean score was *high* on control relative to other clusters' means scores on control and if the cluster's mean score was *low* on the expertise relative to other clusters' mean scores on expertise, this cluster was named authoritarian. If a cluster's mean score was *low* on control relative to other clusters' means score on control and if the cluster's mean score was *low* on the expertise relative to other clusters' mean scores on expertise, this cluster was named chaotic. If a cluster's mean score was *low* on control relative to other clusters' means scores on control and if the cluster's mean score was *high* on the expertise relative to other clusters' mean scores on expertise, this cluster was named collegial.

# Research Question II

Relationships between bureaucratic dimensions and other variables were explored using a variety of statistics. The categorical variables served as independent variables in a series of ANOVAs. In these ANOVAs, bureaucratic dimensions served as continuous dependent variables. The continuous variables served as dependent variables in a series of ANOVAs when each bureaucratic typology was the categorical independent variable. A series of chi-square test were run between categorical variables and the bureaucratic typologies. A series of Pearson correlation coefficients were computed between bureaucratic dimensions and continuous variables. In all analyses, the significance level was.05. A Tukey post-hoc multiple comparison was applied for following significant ANOVAs having more than two levels. *Only significant results were reported in the body of the text for all analyses*.

# Research Question III

Relationships between bureaucratic dimensions and sense of power were explored using a variety of statistics. The sense of power scale score served as the dependent variable in a series of ANOVAs. A Tukey a post-hoc multiple comparison was applied for significant ANOVAs having more than two levels. Only significant results were reported for all ANOVAs.

Pearson correlation coefficients were computed between bureaucratic dimensions and sense of power and regression analyses were run using sense of power as the dependent variable and six bureaucratic dimensions as independent variables. Other continuous variables were used as control variables in the regression analyses. Another set of regression analyses was run using sense of power as the dependent variable and the higher order dimensions as the independent variables. Other continuous variables, again, were used as control variables in regression analyses.
