Figure 1.	Sorghum grain yield responses to side-dress N applications on different soil types. Plot A is characterized as highly responsive, B as moderately responsive, C as non-responsive, and D as negatively responsive	21
Figure 2a & b.	Yield response to side-dress N applications and response surface curves describing estimated relative profit due to N applications (starter band-N and side-dress N) on Suffolk fine sandy loam and Bojac sandy loam in Virginia, 1996.....	22
Figure 2c & d.	Yield response to side-dress N applications and response surface curves describing estimated relative profit due to N applications (starter band-N and side-dress N) on Appling-Cecil complex and Wheeling silt loam in Virginia, 1996.....	23
Figure 3.	Yield response to side-dress N applications and response surface curves describing estimated relative profit due to N applications on Suffolk fine sandy loam and Bojac sandy loam in Virginia, 1996.....	45
Figure 4.	Soil mineral-N (nitrate + ammonium) measured at planting and side-dressing of grain sorghum for eight soils utilized for measuring grain sorghum response to N fertilization.....	62
Figure 5.	Sorghum grain yield increase due to N fertilizer application as a function of residual soil mineral-N measured to 0.9m depth at planting. Regression line is for responsive sites only.....	66
Figure 6a.	Relationship between soil profile (0-0.9m) residual mineral-N sampled at planting and relative yield of four responsive sites in this study. Each data point is the grain yield in check plot treatment presented as % of maximum grain yield.....	68

Figure 6b. Relationship between relative yield in response to various rates of applied N on four responsive sites in this study. Each data point is a mean of 32 data points. Error bars are the standard error of the means..... 68
