A KRUSKAL KATONA THEOREM FOR
CUBICAL COMPLEXES

by
Robert B. Ellis, III

Martin Day, Committee Chair
Department of Mathematics

(ABSTRACT)

The optimal number of faces in cubical complexes which lie in cubes refers to the maximum number of faces that can be constructed from a certain number of faces of lower dimension, or the minimum number of faces necessary to construct a certain number of faces of higher dimension. If \( m \) is the number of faces of dimension \( r \) in a cubical complex, and if \( s > r \) (\( s < r \)), then the maximum (minimum) number of faces of dimension \( s \) that the complex can have is \( m_{(s/r)} + (m - m_{(r/r)})^{(s/r)} \), in terms of upper and lower semipowers. The corresponding formula for simplicial complexes, proved independently by J. B. Kruskal and G. A. Katona, is \( m_{(s/r)} \). A proof of the formula for cubical complexes is given in this paper, of which a flawed version appears in a paper by Bernt Lindström. The \( n \)-tuples which satisfy the optimality conditions for cubical complexes which lie in cubes correspond bijectively with \( f \)-vectors of cubical complexes.
Acknowledgements

I would like to thank Clara Chan, who introduced me to cubical complexes, for her guidance in the production of this work, and for proof-reading the final product.

Also, I would like to thank Ezra Brown, Martin Day, and Peter Haskell for their participation on my thesis defense committee, and especially Ezra Brown for his advice.

Finally, I am grateful to Bernt Lindström for his previous work on this subject. The main result is an extension of the formulas and theorems that he developed.

List of Figures

1 A cubical complex consisting of 0,1, and 2-dimensional faces sits in the 3-cube. 3

2 The cubical complex of Figure 1 appears here in the context of a 3-dimensional binary lattice. 5
3 The set of 1-faces from Figure 1, $S_1$, appears in (a). The boundary set $\partial S_1$ appears in (b), and the coboundary set $\partial^{-1}S_1$ is represented in (c).

4 A set of 2-faces, $S_2$, appears in (a), along with its boundary set of 1-faces. The replacement set, $RS_2$, appears in (b), along with its boundary set of 1-faces.

5 A set, $S_1$, of 1-faces of the 3-cube appears in (a); (a)-(d) are the first four members of the restricted replacement sequence $S_1 = S_1^0$, $R_1S_1^0 = S_1^1$, $R_2S_1^1 = S_1^2$, $R_3S_1^2 = S_1^3$, ..., which becomes constant after the third member.

6 The set $S_1^3$, from Example 5 and the set $RS_1$ are depicted in (a) and (b), respectively, with selected boundary elements.

7 A set of 2-faces, $S_2$, appears in (a), and the vertices of the boundary $\partial^2 S_2$ appear in (b). After the replacement operator is applied to $S_r$, $RS_r$ is depicted in (c), with its smaller number of boundary vertices $\partial^2 RS_r$ in (d).

8 The simplicial complex consists of the tetrahedron $DEFG$, the triangle $ABC$, the edge $BD$, and all subfaces of these faces.

9 Theorem 3 fails for this cubical complex.

1 Some Computational Results for Theorem 2.

2 Some Computational Results for Theorem 3.
1 Introduction

Some popular puzzles involve creating the maximum number of triangles or squares out of a given number of edges. For instance, how many squares could one construct using nine edges? The answer, three, is seen readily enough if the third dimension is utilized and the three squares meet at a single point. A closed formula for determining this and similar solutions would certainly be of interest. In fact, G. A. Katona in [1] and J. B. Kruskal in [3] independently proved a closed formula for the question of creating triangles out of edges, and for other questions concerning faces of certain dimensions of simplicial complexes. As a result of knowing so closely how faces of different dimensions are related in simplicial complexes, a complete characterization of simplicial complexes in terms of the number of possible faces of certain dimension resulted. This characterization is most commonly viewed as concerning the f-vectors of simplicial complexes - the tuples that store the number of faces of each dimension that the corresponding simplicial complexes have. Bernt Lindström proposes a solution in [4] for the question of creating squares out of edges, and all similar questions for cubical complexes which lie in cubes (from this point all cubical complexes discussed are assumed to lie in cubes unless otherwise stated). Lindström’s result is correct, but his proof contains a flaw (pp. 248-9). The formulation of the main result in Section 5 depends on defining a total order on cubical complexes and showing that for the optimality conditions of the main result, it may be assumed that the faces of the cube are lowest possible in the total order. This assumption is labelled the crucial inclusion and is presented in Section 3; however, this section contains many technical details (including a correction of the flaw) which the reader may desire to skip in favor of the more concrete results of Sections 4-6. Indeed, as long as the background material of Section 2 is understood, there is no serious loss of coherency from proceeding in this fashion. In the same vein, proofs of several technical lemmas are relegated to the Appendix. The
corresponding result for simplicial complexes is reviewed in Section 4, and after the main result is presented in Section 5, a complete characterization of $f$-vectors of cubical complexes which lie in cubes is derived.

2 Background

Definition. A cubical complex $C$ is a set of faces of an $n$-dimensional cube with the property that if $F \subseteq C$ is a face of dimension $r$, where $0 \leq r \leq n$, then all lower dimensional faces contained in $F$ are also in $C$.

Note that this definition of a cubical complex restricts attention to those complexes which lie in cubes. This embedding provides a structure by which the optimal number of faces in a cubical complex can be determined. To take advantage of this structure, the labelings of vertices and the definitions of faces of a cubical complex must be made explicit. The $2^n$ vertices of the $n$-cube in which a complex is embedded are labelled in a customary fashion; the vertex $(x_1 \ldots x_n)$, where $x_k \in \{0,1\}$ for all $k$ is labelled $v_i$, where

$$i = \sum_{k=1}^{n} x_k 2^{n-k}.$$  

This labelling allows the following partial order on the vertices. If $v_i = (x_1 \ldots x_n)$ and $v_j = (y_1 \ldots y_n)$, then $v_i < v_j$ if $x_k \leq y_k$ for all $k$, and $v_i \neq v_j$. To prove the main result of this paper it is necessary to determine what the faces of a cubical complex are and to define a total ordering on the faces of the $n$-cube.

Example 1. The object in Figure 1 can be viewed as a cubical complex which sits in the $3$-cube (indicated by the dashed lines). The members of the complex are the square $ABDC$; the lines $AB$, $AC$, $BD$, $CD$, and $CE$; the vertices $A$, $B$, $C$, $D$, $E$, and $F$; and the empty set. The square is the 2-dimensional face, the lines are the 1-dimensional faces, and the vertices are the 0-dimensional faces of the complex. Note that $AB$ is an explicit member of the complex despite $ABDC$ already having
Figure 1: A cubical complex consisting of 0, 1, and 2-dimensional faces sits in the 3-cube.

been given as a member. This satisfies the definition of cubical complexes in that all faces belonging to other faces of higher dimension which are in the complex must also be in the complex. In set notation, the complex in Figure 1 is written as

\[ \{ ABDC, AB, AC, BD, CD, CE, A, B, C, D, E, F, \emptyset \}. \]

The complex can also be viewed as having been generated by its highest dimensional faces which are not contained in any other faces, written as

\[ (ABEC, CE, F). \]

**Definition.** A nonempty face of a cubical complex \( C \) is denoted \( w_{ij} \), where \( v_i = (x_1 \ldots x_n) \) and \( v_j = (y_1 \ldots y_n) \) are the vertices of the faces such that \( v_i < v_k < v_j \) for all other vertices in the face. The empty face is denoted by the empty set. The face \( w_{ij} \) can be written as \( w_{ij} = (x_1 \ldots x_n, y_1 \ldots y_n) \) or as

\[
    w_{ij} = \begin{pmatrix} x_1 \ldots x_n \\ y_1 \ldots y_n \end{pmatrix}.
\]
The empty set is allowed to be a face, of course, because of closure considerations. Also, it is desirable to be able to represent any vertex \( (x_1 \ldots x_n) \) as a 0-dimensional face by writing \( w_{ii} = (x_1 \ldots x_n, x_1 \ldots x_n) \). Note that the \( n \)-dimensional cube is also the face \( w_{02^n} = (0 \ldots 0, 1 \ldots 1) \).

The total ordering on the faces of the \( n \)-cube relies upon the labelling of the vertices which determine the faces. If \( w_{i_1 j_1} \neq w_{i_2 j_2} \) are two faces of the \( n \) cube, then they are ordered by

\[
w_{i_1 j_1} < w_{i_2 j_2} \quad \text{if} \quad j_1 < j_2 \quad \text{or} \quad j_1 = j_2 \quad \text{and} \quad i_2 < i_1.
\]

**Definition.** Let \( T \) be a finite set with a total order defined on it. A set \( I \subseteq T \) is called initial if \( I \) consists of the first \( |I| \) elements of \( T \) in the total order.

The idea of an initial wset \( S_r \) of \( r \)-faces of the \( n \)-cube, or the first \( |S_r| \) \( r \)-faces of the \( n \)-cube, will be useful in proving Theorems 1 and 2.

A face \( w_{ij} \) has as its subfaces the empty set and all faces \( w_{jh} \) such that \( i \leq g \leq j \) since all vertices \( v_k \notin \{v_i, v_j\} \) of the face \( w_{ij} \) have \( v_i \) as an ancestor and \( v_j \) as a descendent in the partial ordering on vertices. This is convenient for the total ordering on vertices since all nonempty subfaces \( w_{gh} \) of \( w_{ij} \) satisfy \( w_{gh} \leq w_{ij} \). The idea of dimension of a face is now made precise.

**Definition.** The dimension of a face \( w_{ij} = (x_1 \ldots x_n, y_1 \ldots y_n) \) in a cubical complex is \( r = \sum_{k=1}^{n} (y_k - x_k) \); \( w_{ij} \) is called an \( r \)-face of the cubical complex.

**Example 2.** The cubical complex in Figure 1 can be viewed as a set of faces \( w_{ij} \) sitting in a 3-dimensional binary lattice. After the vertices are labelled, it is straightforward to label the faces; this new vertex labelling appears in Figure 2. From the previous definitions, the complex can be written in ascending total order as

\[
\{ \emptyset, \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 0 & 1 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \end{pmatrix}, \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 1 \end{pmatrix}, \begin{pmatrix} 0 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix}, \begin{pmatrix} 0 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix} \}.
\]
Figure 2: The cubical complex of Figure 1 appears here in the context of a 3-dimensional binary lattice.

\[
\left\{ \begin{array}{lllllllll}
010 & 001 & 000 & 110 & 010 & 111 \\
011 & 011 & 110 & 110 & 111 &
\end{array} \right\}
\]

If the binary vertices are converted to positive integers in the standard fashion with the most significant bit on the left, the complex in Figure 2 can be written as

\[
\{ \emptyset, w_{00}, w_{11}, w_{01}, w_{22}, w_{03}, w_{23}, w_{13}, w_{09}, w_{68}, w_{26}, w_{77} \},
\]

Finally, in the notation of a complex generated by its largest faces not contained in other faces, the complex can be written as generated by a 2-face, a 1-face, and a 0-face, respectively:

\[
\langle w_{33}, w_{26}, w_{77} \rangle.
\]

By definition if a cubical complex \( C \) contains an \( r \)-face \( w_{ij} \), it also contains all of the \((r-1)\)-faces contained in \( w_{ij} \). These faces are called the boundary of \( w_{ij} \) and are denoted by \( \partial w_{ij} \), where \( \partial \) is the boundary operator. Furthermore, if \( S \) is a set of faces of a cubical complex, then \( \partial S \), the boundary of \( S \), is defined to be the union
of the boundaries of each face in $S$. It is convenient to use $S_r$ to denote the set of $r$-faces of a cubical complex; whence $\partial S_r$, the boundary of $S_r$, is the set of $(r - 1)$ faces, each of which is in the boundary of some $r$-face in $S_r$. Conversely, $\partial^{-1} S$, the coboundary of $S_r$, is defined to be the largest set of $(r + 1)$-faces, the boundary of which is contained in $S_r$. In other words, $\partial^{-1} S_r$ is the largest set of $(r + 1)$-faces $T_{r+1}$ such that $\partial T_{r+1} \subseteq S_r$. By this definition, the boundary of a vertex (a 0-face) is the empty set. The operators $\partial$ and $\partial^{-1}$ applied $p$ times each are written respectively as $\partial^p$(the $p$th boundary) and $\partial^{-p}$(the $p$th coboundary).

![Diagrams](image)

Figure 3: The set of 1-faces from Figure 1, $S_1$, appears in (a). The boundary set $\partial S_1$ appears in (b), and the coboundary set $\partial^{-1} S_1$ is represented in (c).

**Example 3.** Consider the set $S_1$ of the 1-dimensional faces of the complex in Figure 2. By inspection it is easy to verify the following:

$$S_1 = \{w_{01}, w_{02}, w_{23}, w_{13}, w_{26}\}.$$

The set of faces of $S_1$ is represented in Figure 3(a). The boundary of $S_1$, or all the vertices contained in the edges of $S_1$, is $\{w_{00}, w_{11}, w_{22}, w_{33}, w_{66}\}$, and is represented in Figure 3(b). Verification of $\partial^{-1} \partial S_1 = S_1$ can be done empirically. The coboundary of $S_1$ is the set of 2-faces, $\{w_{03}\}$, and is represented in Figure 3(c). Note that the boundary of the face in Figure 3(c) is not $S_1$; no 2-face arises from the 1-face $w_{26}$ in
$S_1$, since other required 1-faces in the boundary of the 2-face are absent from 3(a). This illustrates empirically the containment $\partial \mathcal{D}^{-1} S_1 \subseteq S_1$.

The total order on the faces of the $n$-cube lends an inherited total order to the $r$-faces of the $n$-cube. For this reason, if $S_r$ is a set of $r$-faces, the $|S_r|$ first $r$-faces in the total order may be considered; this set is called $RS_r$, where $R$ is the replacement operator. For any face $w_{ij} = (v_i, v_j) = (x_1 \ldots x_n, y_1 \ldots y_n)$, the three possibilities for $(x_k, y_k)$, for all $k$, are $(0, 0)$, $(0, 1)$, and $(1, 1)$, since $v_i \prec v_j$ or $v_i = v_j$. The total order on the set of $r$-faces $S_r$ of the $n$-cube can be further restricted to $r$-faces which have the $k$th coordinate $(x_k, y_k)$, resulting in three disjoint sets which are labelled $S_{r,k}(x_k, y_k)$ where $k$ is fixed and $(x_k, y_k) \in \{(0, 0), (0, 1), (1, 1)\}$. Furthermore, the restricted replacement operator $R_k$ acting on $S_r$ sends $S_{r,k}(x_k, y_k)$ to the $|S_{r,k}(x_k, y_k)|$ lowest $r$-faces whose $k$th coordinate is fixed at $(x_k, y_k)$, and returns the union over the three possibilities for $(x_k, y_k)$.

![Diagram](image)

Figure 4: A set of 2-faces, $S_2$, appears in (a), along with its boundary set of 1-faces. The replacement set, $RS_2$, appears in (b), along with its boundary set of 1-faces.

**Example 4.** In a sense, the replacement operator $R$ acts on a set of $r$-faces by compressing them into the smallest possible configuration (the "smallness" is de-
termed by considering the total order). Figure 4(a) depicts three 2-dimensional faces and the ten 1-dimensional faces of their boundary sitting in the 3-cube. Letting \( S_2 \) be the 2-dimensional faces of Figure 4(a) gives \( S_2 = \{w_{06}, w_{47}, w_{17}\} \). The boundary of \( S_2 \) is \( \partial S_2 = \{w_{02}, w_{13}, w_{04}, w_{45}, w_{15}, w_{46}, w_{26}, w_{67}, w_{57}, w_{37}\} \), arranged in ascending total order. Figure 4(b) represents the replacement of \( S_2 \), or \( RS_2 \). The lowest three 2-faces in the total order are \( RS_2 = \{w_{03}, w_{05}, w_{06}\} \). The boundary of \( RS_2 \) is \( \partial RS_2 = \{w_{01}, w_{02}, w_{23}, w_{13}, w_{04}, w_{45}, w_{15}, w_{46}, w_{26}\} \), arranged in ascending total order. Note that \( \partial RS_2 \) is smaller than \( \partial S_2 \).

3 The Crucial Inclusion

The result of Lindstöm’s paper hinges the following theorem involving boundaries of sets of \( r \)-faces, which appears as Theorem 1 in [4].

**Theorem 1.** Let \( S_r \) be a set of \( r \)-faces in the \( n \)-cube, with \( 1 \leq r \leq n \). Let \( \partial \) and \( R \) be the boundary and replacement operators defined previously. Then

\[
\partial RS_r \subseteq R\partial S_r.
\]

This theorem will also be referred to as the crucial inclusion. From this theorem arises a corollary which appears as Corollary 1 in [4], and allows the computations for the main result of this paper in Section 5.

**Corollary 1.** \( |\partial^p RS_r| \leq |\partial^p S_r| \) and \( |\partial^{-p} S_r| \leq |\partial^{-p} RS_r| \), where \( p \) is a positive integer.

Corollary 1 states first that the size of the \( p \)th boundary of an initial set of \( r \)-faces \( RS_r \) is no larger than the size of the \( p \)th boundary of the original set of \( r \)-faces \( S_r \). If \( s \) is the dimension of the faces in \( |\partial^p RS_r| \), then the smallest number of \( s \)-faces required to compose the boundary set \( \partial^p S_r \) is the number of \( s \)-faces in the boundary set \( \partial^p RS_r \). Thus for the main result, a formula must be established
which counts the number of $s$-faces in the boundary of an initial set $RS_r$ of $r$-faces. Similarly, the second part of the Corollary determines that the number of $s$-faces in the $p$th coboundary set $\partial^{-p}S_r$ is bounded above by the number of $s$-faces in the $p$th coboundary set $\partial^{-p}RS_r$. It happens that the above mentioned formula also counts the number of $s$-faces in the coboundary of an initial set $RS_r$ of $r$-faces.

The proof of this corollary, which appears in [4], follows the proof of Theorem 1.

**Proof of Theorem 1.** The proof of Theorem 1 has two parts. First, it is necessary to show that the size of $\partial RS_r$ is no greater than the size of $\partial S_r$. From there, it is sufficient to show that $\partial RS_r$ is an initial set of $(r - 1)$-faces, as by definition $R\partial S_r$ is an initial set of $(r - 1)$-faces.

The proof of $|\partial RS_r| \leq |\partial S_r|$ is by induction on the dimension $n$ and occurs in two stages ($n = 1$ and $n = 2$ have a small number of cases for which the theorem can be verified in a straightforward manner). First, the restricted operator $R_k$ is applied to $S_r$ for varying values of $k$ until the resulting set of $r$-faces is constant. It must be shown that the resulting set has a boundary that is no larger than that of $S_r$. This is done by showing that during each restricted replacement step the size of the boundary of the set of $r$-faces does not increase. Second, since the resulting set in general is not equal to $RS_r$, it must be shown that the size of the boundary of $RS_r$ is no larger than the size of the boundary of the resulting set.

### 3.1 The Sequential Replacement

Since there is a total ordering on the faces of the $n$-cube, each face can be associated with a positive integer; i.e., there is a mapping $\theta$ from the faces of the $n$-cube to a finite subset of the positive integers which preserves the total order on the faces, giving $\theta(w_{gh}) < \theta(w_{ij})$ whenever $w_{gh}$ and $w_{ij}$ are faces such that $w_{gh} < w_{ij}$ in the total order. Furthermore, for a set of $r$-faces $S_r$, define $\text{sum}(S_r)$ to be the sum of
the numbers associated with the faces of $S_r$, or

$$sum(S_r) = \sum_{w_{ij} \in S_r} \theta(w_{ij}).$$

As the restricted replacement operator $R_k$ may only replace $r$-faces of $S_r$ with $r$ faces that are lower in the total order, it follows that $sum(R_k S_r) \leq sum(S_r)$ for any index $k$ fixed between 1 and $n$. This fact determines that the sequence constructed below will eventually become constant, as it is monotonically decreasing and bounded below by $sum(RS_r)$.

If $S_r$ is an arbitrary set of $r$-faces of the $n$-cube, apply the restricted replacement operators $R_1, R_2, \ldots, R_n, R_1, \ldots$ repeatedly to obtain the infinite sequence

$$S^0_r = S_r, S^1_r = R_1 S^0_r, \ldots, S^n_r = R_n S^{n-1}_r, S^{n+1}_r = R_1 S^n_r, \ldots$$

If $S^{i+1}_r \neq S^i_r$ it follows that $sum(S^{i+1}_r) < sum(S^i_r)$. It is not difficult to see that if at some point in the sequence the set $S^i_r$ is constant under the application of $R_1, R_2, \ldots, R_n$, then the sequence itself will be constant from that set onward. This establishes the existence of an index $q$ such that $S^q_r = S^{q+1}_r = \ldots = S^{q+n}_r = \ldots$.

**Example 5.** Let $S_1$ be the 1-faces of the cubical complex in Figure 5(a). Then

$$S_1 = \left\{ \begin{pmatrix} 001 \\ 011 \end{pmatrix}, \begin{pmatrix} 010 \\ 110 \end{pmatrix}, \begin{pmatrix} 110 \\ 111 \end{pmatrix}, \begin{pmatrix} 101 \\ 111 \end{pmatrix} \right\}$$

(all sets are written in increasing total order). Now consider $S_1 = S^0_1$ as the first set in the sequence of fixed coordinate replacements. The next set in the sequence, $R_1 S^0_1 = S^1_1$, is depicted in Figure 5(b). The operator $R_1$ acts on $S_1$ by fixing the first coordinate. The face $\begin{pmatrix} 001 \\ 011 \end{pmatrix}$ of $S_1$ is replaced with the face $\begin{pmatrix} 000 \\ 001 \end{pmatrix}$, which is the lowest 1-face in the total order with the first coordinate fixed at (0,0). Similary, $\begin{pmatrix} 110 \\ 111 \end{pmatrix}$ and $\begin{pmatrix} 101 \\ 111 \end{pmatrix}$ are replaced by $\begin{pmatrix} 100 \\ 100 \end{pmatrix}$ and $\begin{pmatrix} 101 \\ 110 \end{pmatrix}$. Finally, $\begin{pmatrix} 010 \\ 110 \end{pmatrix}$ is replaced by $\begin{pmatrix} 000 \\ 100 \end{pmatrix}$. The set

$$S^1_1 = \left\{ \begin{pmatrix} 000 \\ 001 \end{pmatrix}, \begin{pmatrix} 000 \\ 100 \end{pmatrix}, \begin{pmatrix} 100 \\ 101 \end{pmatrix}, \begin{pmatrix} 100 \\ 110 \end{pmatrix} \right\}$$

10
is obtained, as shown in Figure 5(b). The next step in the sequential replacement is to fix the 2nd coordinate, finding the set \( R_2 S_1^1 = S_1^2 \). This set is represented in Figure 5(c); i.e.,

\[
S_1^2 = \left\{ \begin{pmatrix} 000 \\ 001 \end{pmatrix}, \begin{pmatrix} 000 \\ 010 \end{pmatrix}, \begin{pmatrix} 000 \\ 100 \end{pmatrix}, \begin{pmatrix} 100 \\ 101 \end{pmatrix} \right\}.
\]

The sequence becomes constant with the fourth member, \( R_3 S_1^2 = S_1^3 \), depicted in Figure 5(d); i.e.,

\[
S_1^3 = \left\{ \begin{pmatrix} 000 \\ 001 \end{pmatrix}, \begin{pmatrix} 000 \\ 010 \end{pmatrix}, \begin{pmatrix} 010 \\ 011 \end{pmatrix}, \begin{pmatrix} 000 \\ 100 \end{pmatrix} \right\}.
\]

Note that \( S_1^3 \) is not an initial set of 1-faces of the 3-cube, because \( w_{13} < w_{04} \). Also, the number of faces (vertices) of the boundary does not increase as the sequence progresses.

Figure 5: A set, \( S_1 \), of 1-faces of the 3-cube appears in (a); (a)-(d) are the first four members of the restricted replacement sequence \( S_1 = S_1^0, R_1 S_1^0 = S_1^1, R_2 S_1^1 = S_1^2, R_3 S_1^2 = S_1^3 \), ..., which becomes constant after the third member.

To show \( |\partial S_r^t| \leq |\partial S_r| \) it is sufficient to show that for each index \( l \), \( |\partial S_r^{l+1}| \leq |\partial S_r^l| \); in other words, the size of the boundary set does not increase along the sequence. Without loss of generality, \( l \) can be assumed to be less than \( n \), since the issue of interest is the coordinate fixed by the restricted replacement operator; the set \( S_r^{l+1} \) is obtained from the set \( S_r^l \) by applying the restricted replacement operator \( R_{(l \mod n)+1} \) to \( S_r^l \).
Given two adjacent sets in the sequence which may be denoted as $S_r^{l-1}$ and $R_iS_r^{l-1}$, showing that the number $(r - 1)$-faces of the boundary does not increase is equivalent to showing $|\partial R_iS_r^{l-1}| \leq |\partial S_r^{l-1}|$, which is equivalent to showing

$$|\partial R_iS_r^{l-1}(0,0) \cup \partial R_iS_r^{l-1}(0,1) \cup \partial R_iS_r^{l-1}(1,1)|$$

$$\leq |\partial S_r^{l-1}(0,0) \cup \partial S_r^{l-1}(0,1) \cup \partial S_r^{l-1}(1,1)|.$$

By inclusion-exclusion, this is equivalent to showing the following:

$$|\partial R_iS_r^{l-1}(0,0)| + |\partial R_iS_r^{l-1}(0,1)| + |\partial R_iS_r^{l-1}(1,1)| -$$

$$|\partial R_iS_r^{l-1}(0,0) \cap \partial R_iS_r^{l-1}(0,1)| - |\partial R_iS_r^{l-1}(0,1) \cap \partial R_iS_r^{l-1}(1,1)| -$$

$$|\partial R_iS_r^{l-1}(0,0) \cap \partial R_iS_r^{l-1}(1,1)| +$$

$$|\partial R_iS_r^{l-1}(0,0) \cap \partial R_iS_r^{l-1}(0,1) \cap \partial R_iS_r^{l-1}(1,1)|$$

$$\leq |\partial S_r^{l-1}(0,0)| + |\partial S_r^{l-1}(0,1)| + |\partial S_r^{l-1}(1,1)| -$$

$$|\partial S_r^{l-1}(0,0) \cap \partial S_r^{l-1}(0,1)| - |\partial S_r^{l-1}(0,1) \cap \partial S_r^{l-1}(1,1)| -$$

$$|\partial S_r^{l-1}(0,0) \cap \partial S_r^{l-1}(1,1)| +$$

$$|\partial S_r^{l-1}(0,0) \cap \partial S_r^{l-1}(0,1) \cap \partial S_r^{l-1}(1,1)|.$$

(1)

Lindström shows in [4] that the following equations hold:

$$|\partial R_iS_r^{l-1}(0,0)| \leq |\partial S_r^{l-1}(0,0)|$$

$$|\partial R_iS_r^{l-1}(0,1)| \leq |\partial S_r^{l-1}(0,1)|$$

$$|\partial R_iS_r^{l-1}(1,1)| \leq |\partial S_r^{l-1}(1,1)|$$

(2)

by an argument which invokes the induction hypothesis on the original theorem (recall that induction is on the dimension, $n$, of the $n$-cube in which all of the faces are imbedded). Of course, (2) does not necessarily imply (1). The proof of this implication, omitted in [4], is included here.

First, it can be shown that two terms in either side of (1) vanish; i.e.,

$$|\partial R_iS_r^{l-1}(0,0) \cap \partial R_iS_r^{l-1}(0,1) \cap \partial R_iS_r^{l-1}(1,1)| = 0$$
\begin{align*}
|\partial R_i S^{l-1}_{r,j}(0,0) \cap \partial R_i S^{l-1}_{r,j}(1,1)| &= 0 \\
|\partial S^{l-1}_{r,j}(0,0) \cap \partial S^{l-1}_{r,j}(0,1) \cap \partial S^{l-1}_{r,j}(1,1)| &= 0 \\
|\partial S^{l-1}_{r,j}(0,0) \cap \partial S^{l-1}_{r,j}(1,1)| &= 0.
\end{align*}

This is because all \((r-1)\)-faces of the boundary set \(\partial R_i S^{l-1}_{r,j}(0,0)\) must have \((0,0)\) in the \(l\)th coordinate, and all \((r-1)\)-faces of the boundary set \(\partial R_i S^{l-1}_{r,j}(1,1)\) must have \((1,1)\) as the \(l\)th coordinate, making the two boundary sets disjoint. Similarly, \(\partial S^{l-1}_{r,j}(0,0) \cap \partial S^{l-1}_{r,j}(1,1) = \emptyset\). From this the reduced equation from (1) is obtained:

\begin{align}
|\partial R_i S^{l-1}_{r,j}(0,0)| + |\partial R_i S^{l-1}_{r,j}(0,1)| + |\partial R_i S^{l-1}_{r,j}(1,1)| - \\
|\partial R_i S^{l-1}_{r,j}(0,0) \cap \partial R_i S^{l-1}_{r,j}(0,1)| - |\partial R_i S^{l-1}_{r,j}(0,1) \cap \partial R_i S^{l-1}_{r,j}(1,1)| \\
\leq |\partial S^{l-1}_{r,j}(0,0)| + |\partial S^{l-1}_{r,j}(0,1)| + |\partial S^{l-1}_{r,j}(1,1)| - \\
|\partial S^{l-1}_{r,j}(0,0) \cap \partial S^{l-1}_{r,j}(0,1)| - |\partial S^{l-1}_{r,j}(0,1) \cap \partial S^{l-1}_{r,j}(1,1)|. 
\end{align}

(3)

Furthermore, all the \((r-1)\)-faces of the boundary set \(\partial S^{l-1}_{r,j}(0,0)\) have \((0,0)\) as the \(l\)th coordinate; all the \((r-1)\)-faces of the intersection \(\partial S^{l-1}_{r,j}(0,0) \cap \partial S^{l-1}_{r,j}(0,1)\) must be obtained from \(r\)-faces of \(S^{l-1}_{r,j}(0,1)\) which have the \(l\)th coordinate changed from \((0,1)\) to \((0,0)\). This is exactly the set \((\partial_l(0,0)) S^{l-1}_{r,j}(0,1)\), where \(\partial_l(x_1, y_l) S_r\) is defined to be all \((r-1)\)-faces of the boundary set \(\partial S_r\) which have the \(l\)th coordinate fixed at \((x_l, y_l)\). By this and similar reasoning, the following containments are obtained:

\begin{align*}
\partial S^{l-1}_{r,j}(0,0) \cap \partial S^{l-1}_{r,j}(0,1) &\subseteq (\partial_l(0,0)) S^{l-1}_{r,j}(0,1) \\
\partial S^{l-1}_{r,j}(1,1) \cap \partial S^{l-1}_{r,j}(0,1) &\subseteq (\partial_l(1,1)) S^{l-1}_{r,j}(0,1) \\
\partial R_i S^{l-1}_{r,j}(0,0) \cap \partial R_i S^{l-1}_{r,j}(0,1) &\subseteq (\partial_l(0,0)) R_i S^{l-1}_{r,j}(0,1) \\
\partial R_i S^{l-1}_{r,j}(1,1) \cap \partial R_i S^{l-1}_{r,j}(0,1) &\subseteq (\partial_l(1,1)) R_i S^{l-1}_{r,j}(0,1). 
\end{align*}

(4)

Finally, for each of the following two pairs of sets, it can be shown that one set is a subset of the other.

\begin{align}
\{\partial R_i S^{l-1}_{r,j}(0,0), \partial_l(0,0) R_i S^{l-1}_{r,j}(0,1)\} \\
\{\partial R_i S^{l-1}_{r,j}(1,1), \partial_l(1,1) R_i S^{l-1}_{r,j}(0,1)\} 
\end{align}

(5)
By considering the pair of sets $\partial R_i S_{r,l}^{l-1}(0,0)$ and $(\partial_i(0,0)) R_i S_{r,l}^{l-1}(0,1)$ it can be seen that the set $R_i S_{r,l}^{l-1}(0,0)$ is the $|S_{r,l}^{l-1}(0,0)|$ first $r$-faces of the $n$-cube which have the $l$th coordinate fixed at $(0,0)$. If the $l$th position is ignored, the $|S_{r,l}^{l-1}(0,0)|$ first $r$-faces of the $(n-1)$-cube are obtained. By induction on the main theorem, the boundary of this set of $r$-faces of the $(n-1)$-cube is an initial set of $(r-1)$-faces of the $(n-1)$-cube. Restoring the $l$th coordinate of these $(r-1)$-faces at $(0,0)$ gives $\partial R_i S_{r,l}^{l-1}(0,0)$, which exactly correspond to the first $|\partial R_i S_{r,l}^{l-1}(0,0)|$ $(r-1)$-faces of the $n$-cube which have the $l$th coordinate fixed at $(0,0)$. The set $(\partial_i(0,0)) R_i S_{r,l}^{l-1}(0,1)$ is all of the $(r-1)$-faces of $\partial R_i S_{r,l}^{l-1}(0,1)$ which have had the $l$th coordinate changed from $(0,1)$ to $(0,0)$. This corresponds to the $|R_i S_{r,l}^{l-1}(0,1)|$ first $(r-1)$-faces in the $n$-cube which have the $l$th coordinate fixed at $(0,0)$.

Both of these sets are initial sets of $(r-1)$-faces of the $n$-cube with the $l$th coordinate fixed at $(0,0)$; hence one set is a subset of the other. Containment for the second pair of sets is proved similarly.

With the previous information the inequality in (1) can now be proved via the simplification in (3).

(4) implies

$$|\partial S_{r,l}^{l-1}(0,0) \cap \partial S_{r,l}^{l-1}(0,1)| \leq |S_{r,l}^{l-1}(0,1)|$$

$$|\partial S_{r,l}^{l-1}(1,1) \cap \partial S_{r,l}^{l-1}(0,1)| \leq |S_{r,l}^{l-1}(0,1)|;$$

(5) implies

$$|\partial R_i S_{r,l}^{l-1}(0,0) \cap \partial R_i S_{r,l}^{l-1}(0,1)| = \min\{|\partial R_i S_{r,l}^{l-1}(0,0)|, |S_{r,l}^{l-1}(0,1)|\}$$

$$|\partial R_i S_{r,l}^{l-1}(1,1) \cap \partial R_i S_{r,l}^{l-1}(0,1)| = \min\{|\partial R_i S_{r,l}^{l-1}(1,1)|, |S_{r,l}^{l-1}(0,1)|\}. $$

From these, four cases for the inequality in (3) are obtained. In the first case

$$|\partial R_i S_{r,l}^{l-1}(0,0) \cap \partial R_i S_{r,l}^{l-1}(0,1)| = |\partial R_i S_{r,l}^{l-1}(0,0)|$$

and

$$|\partial R_i S_{r,l}^{l-1}(1,1) \cap \partial R_i S_{r,l}^{l-1}(0,1)| = |\partial R_i S_{r,l}^{l-1}(1,1)|$$
imply (3) by the following:

\[
|\partial R_i S_{r,l}^{i-1}(0,0)| + |\partial R_i S_{r,l}^{i-1}(0,1)| - |\partial R_i S_{r,l}^{i-1}(1,0)| + |\partial R_i S_{r,l}^{i-1}(1,1)| - \\
|\partial R_i S_{r,l}^{i-1}(0,0) \cap \partial R_i S_{r,l}^{i-1}(0,1)| - |\partial R_i S_{r,l}^{i-1}(0,1) \cap \partial R_i S_{r,l}^{i-1}(1,1)|
\]

\[
= |\partial R_i S_{r,l}^{i-1}(0,1)|
\]

\[
\leq |\partial S_{r,l}^{i-1}(0,1)| \quad \text{by (2)}
\]

\[
\leq |\partial S_{r,l}^{i-1}(0,0)| + |\partial S_{r,l}^{i-1}(0,1)| + |\partial S_{r,l}^{i-1}(1,1)| - \\
|\partial S_{r,l}^{i-1}(0,0) \cap \partial S_{r,l}^{i-1}(0,1)| - |\partial S_{r,l}^{i-1}(0,1) \cap \partial S_{r,l}^{i-1}(1,1)|,
\]

since the following equations hold:

\[
|\partial S_{r,l}^{i-1}(0,0) \cap \partial S_{r,l}^{i-1}(0,1)| \leq |\partial S_{r,l}^{i-1}(0,0)|
\]

\[
|\partial S_{r,l}^{i-1}(0,1) \cap \partial S_{r,l}^{i-1}(1,1)| \leq |\partial S_{r,l}^{i-1}(1,1)|.
\]

The other cases give the desired result similarly and are omitted.

In conclusion, by (1), it is ascertained that \(|\partial R_i S_{r,l}^{i-1}| \leq |\partial S_{r,l}^{i-1}|\) for arbitrary \(l\) between \(i\) and \(n\). Repeated application of this fact shows that the size of the boundary set is monotonically decreasing along the sequence; it follows that \(|\partial S_r| \leq |\partial S_r'|\), as desired.

### 3.2 The Arbitrary Replacement

After the sequential replacement has been done, for which the size of the boundary of the set of \(r\)-faces does not increase, an arbitrary replacement is done to obtain the initial set of size \(|S_r|\) of \(r\)-faces, since in general, \(RS_r \neq S_r'\). The arbitrary replacement is done by replacing the largest \(r\)-face \((a,a')\) in \(S_r'\) with the smallest \(r\)-face \((b,b')\) not in \(S_r'\) iteratively until \(RS_r' = RS_r\) is obtained. Once again, it must be ascertained that the size of the boundary set of these \(r\)-faces does not increase under this arbitrary replacement. This is achieved by showing that the only possible
candidates for the two faces \((a, a')\) and \((b, b')\) require \(|\partial((S^3_1 - \{(a, a')\}) \cup \{(b, b')\})| \leq |\partial S^3_1|\). A short argument on the iteration of this step results in \(|\partial S_r| \leq |\partial S^3_1|\).

**Example 6.** Consider the sequential replacement on the set \(S_1\) in Example 5. The constant result of the sequential replacement, \(S^3_1\), is not the four lowest 1-faces of the 3-cube. It has been shown that the size of the boundary set does not increase along the restricted replacement sequence, but to satisfy the crucial inclusion, it must also hold that \(S^3_1\) does not have a smaller boundary set than \(RS_1\) (which is also \(RS^3_1\)). There are two differences between the sets \(S^3_1\) and \(RS_1\), which are shown as Figure 6(a) and (b), respectively. \(S^3_1\) contains the face \(\begin{pmatrix} a \\ a' \end{pmatrix} = \begin{pmatrix} 000 \\ 100 \end{pmatrix}\), and \(RS_1\) does not. \(RS_1\) contains the face \(\begin{pmatrix} b \\ b' \end{pmatrix} = \begin{pmatrix} 001 \\ 011 \end{pmatrix}\), and \(S^3_1\) does not.

![Diagram](image)

**Figure 6:** The set \(S^3_1\), from Example 5 and the set \(RS_1\) are depicted in (a) and (b), respectively, with selected boundary elements.

Now consider the effect of removing \((a, a')\) from \(S^3_1\) and adding \((b, b')\) in its place. The boundaries of \((a, a')\) and \((b, b')\) are denoted in Figure 6. Removing \((a, a')\) from \(S^3_1\) removes the boundary vertex \(\begin{pmatrix} 100 \\ 100 \end{pmatrix}\). The vertices in the boundary of \((b, b')\) are already contained in the boundary set \(\partial(S^3_1 - \{(a, a')\})\); hence no boundary elements are added when the face \((b, b')\) is added to \(S^3_1 - \{(a, a')\}\). Since \((S^3_1 - \{(a, a')\}) \cup \{(b, b')\}) \subseteq \cdots \subseteq \cdots \subseteq (S^3_1 - \{(a, a')\}) \cup \{(b, b')\})

16
\{(a, a')\} \cup \{(b, b')\} = RS_1, S_1^3 \text{ a larger boundary set than } RS_1. \text{ The required inequality, } |\partial RS_1| \leq |\partial S_1|, \text{ is satisfied.}

Recall that \(S_?^r\) is the set of \(r\)-faces obtained from \(S_r\) by the sequential replacement step. Let \((a, a')\) be the largest \(r\)-face in \(S_?^r\) and let \((b, b')\) be the smallest \(r\)-face no in \(S_?^r\). To show \(|\partial RS_r| \leq |\partial S_?^r| \leq |\partial S_r|\), it is sufficient to show that whenever \(S_?^r \neq RS_r\), replacing \((a, a')\) with \((b, b')\) does not increase the size of the boundary of the resultant set of \(r\)-faces. The two cases that arise are \(a' = b'\) and \(a' > b'\).

**Case 1.** Let \(a' = b' = (1 \ldots 1)\), or else there is an index \(j\) for which \(a'_j = b'_j = 0\). Then \(a_j = b_j = 0\) since \((1, 0)\) pairs are illegal, and \((a_j, a'_j) = (b_j, b'_j) = (0, 0)\), and \((a, a')\) would have been replaced with \((b, b')\) in the sequential replacement step. Furthermore, the following properties must hold:

1. \(a_i \neq b_i \forall i \in \{1 \ldots n\}\); otherwise \((a, a')\) (or some other \(r\)-face) would have been replaced with \((b, b')\) in the sequential replacement, and \((b, b')\) would be in \(S_?^r\).

2. \(a_1 = 0\) and \(b_1 = 1\); otherwise \(a < b\) and \((a, a') < (b, b')\), which violates the assumed order on \((a, a')\) and \((b, b')\).

3. \(n\) is even and \(r = n/2\); otherwise, without loss of generality, there are more \((1, 1)\) coordinates than \((0, 1)\) coordinates of both \((a, a')\) and \((b, b')\); however, in this case there must be an index \(j\) for which \((a_j, a'_j) = (b_j, b'_j) = (1, 1)\). Then \((a, a')\) would have been replaced with \((b, b')\) in the sequential replacement step.

In particular, if \(n = 2\), the above conditions require \(\begin{pmatrix} b \\ b' \end{pmatrix} = \begin{pmatrix} 10 \\ 11 \end{pmatrix}\) and \(\begin{pmatrix} a \\ a' \end{pmatrix} = \begin{pmatrix} 01 \\ 11 \end{pmatrix}\). This gives \(\partial \{(b, b')\} = \left\{ \begin{pmatrix} 10 \\ 10 \end{pmatrix}, \begin{pmatrix} 11 \\ 11 \end{pmatrix} \right\}\) and \(\partial \{(a, a')\} = \left\{ \begin{pmatrix} 01 \\ 01 \end{pmatrix}, \begin{pmatrix} 11 \\ 11 \end{pmatrix} \right\}\). But the boundary \(\begin{pmatrix} 10 \\ 10 \end{pmatrix}\) also comes from the \(r\)-face \(\begin{pmatrix} 00 \\ 10 \end{pmatrix}\); hence \(\partial ((S_?^r \setminus \{(a, a')\}) \cup \{(b, b')\}) \leq \partial S_?^r\), as desired, since \(\begin{pmatrix} 00 \\ 10 \end{pmatrix}\) \(\in S_?^r\) by assumption.
For the case \( n > 2 \), i.e., \( n \geq 4 \), except for the first coordinate of \((a, a')\) which has been shown to be \((0, 1)\), there can be no \((0, 1)\) coordinates to the left of \((1, 1)\) coordinates. Hence

\[
\begin{pmatrix}
  a \\
  a' \\
  b \\
  b'
\end{pmatrix}
= 
\begin{pmatrix}
  01\ldots10\ldots0 \\
  11\ldots11\ldots1 \\
  10\ldots01\ldots1 \\
  11\ldots11\ldots1
\end{pmatrix}
\]

and

Otherwise, if there exist indices \(2 \leq j < k < n\) for which \((a_j, a'_j) = (0, 1)\) and \((a_k, a'_k) = (1, 1)\), define \((d, d')\) by \((d_j, d'_j) = (1, 1)\), \((d_k, d'_k) = (0, 1)\) and \((d_i, d'_i) = (a_i, a'_i)\) for all other indices \(i \in \{1, \ldots, n\}\) to demonstrate a face which satisfies \((b, b') < (d, d') < (a, a')\); hence, the sequential replacement step would have replaced \((a, a')\) (or some other face) with \((b, b')\), which is a contradiction.

Now it will be shown that the size of the boundary of \(S^n_2 - \{(a, a')\}\) does not increase when \((b, b')\) is added. Elements of the boundary of \((b, b')\) are obtained by changing \((0, 1)\) pairs to either \((1, 1)\) or \((0, 0)\); thus fix an index \(l \in \{2, \ldots, \frac{n}{2} + 1\}\) whose coordinate is to be changed.

1. If \((b_l, b'_l)\) is changed to \((1, 1)\), define the face \((c, c')\) by \((c_l, c'_l) = (1, 1)\), \((c_i, c'_i) = (0, 1)\) and \((c_i, c'_i) = (b_l, b'_l)\) for all other indices \(i \in \{1, \ldots, n\}\). Then \((c, c')\) contains the same boundary element and is an \(r\)-face smaller than \((b, b')\), since \(c > b\); hence \((c, c')\) is in \(R^n_2\) by definition of \((b, b')\), and and this boundary element is not added to \(\partial(S^n_2 - \{(a, a')\})\) when \((b, b')\) is added to \(S^n_2 - \{(a, a')\}\).

2. Similarly, if \((b_l, b'_l)\) is changed to \((0, 0)\), no boundary element is added to \(\partial(S^n_2 - \{(a, a')\})\) when \((b, b')\) is added to \(S^n_2 - \{(a, a')\}\).

In either instance, \((S^n_2 - \{(a, a')\}) \cup \{(b, b')\}\) has no larger a boundary than \(S^n_2\) since removing \((a, a')\) from the set can only take away boundary elements and it has been shown that adding \((b, b')\) to the set does not increase the number of boundaries.
Case 2. Let $a' > b'$. As Lindström shows in [4], there can be only one index $l$ for which $a'_l > b'_l$. For all other indices $i$, $a'_i \leq b'_i$. Otherwise, there are two indices $1 \leq j < k \leq n$ for which $a'_j > b'_j$ and $a'_k > b'_k$. Without loss of generality, $n > 2$, since otherwise $(a, a')$ and $(b, b')$ are vertices with empty boundary sets. For these two indices, $(a_j, b'_j) = (b_k, b'_k) = (0, 0)$. If $(a_k, a'_k) = (1, 1)$, define the face $(d, d')$ by $(d_k, d'_k) = (a_k, a'_k)$ and $(d_i, d'_i) = (b_i, b'_i)$ for all other indices $i \in \{1, \ldots, n\}$. Then $(d, d')$ is an $r$-face which satisfies the inequality $(b, b') < (d, d') < (a, a')$, and since $(d, d')$ has coordinates in common with both $(a, a')$ and $(b, b')$, this is a contradiction since the sequential replacement would have replaced $(a, a')$ with $(b, b')$. Similarly, if $(a_k, a'_k) = (0, 1)$, choose an index $m$ for which $(b, b') = (0, 1)$ and define $(d, d')$ as before except $(d_m, d'_m) = (1, 1)$ in order to keep the dimension of the face $(d, d')$ fixed at $r$ and obtain the same contradiction through the sequential replacement.

From this point in this case, Lindström's proof is flawed, and is replaced here with a new proof. Furthermore, as in the previous case $(a, a')$ may not have a $(0, 1)$ pair to the left of a $(1, 1)$ pair; i.e., there cannot be $1 \leq j < k \leq n$ for which $(a_j, a'_j) = (0, 1)$ and $(a_k, a'_k) = (1, 1)$. The cases for $n = 2$ are few and easily verified. Otherwise, for $n > 2$, a contradiction is obtained by defining $(d, d')$ as follows: $(d_j, d'_j) = (1, 1)$, $(d_k, d'_k) = (0, 1)$, and $(d_i, d'_i) = (a_i, a'_i)$ for all other indices $i$. The following configuration is obtained for $(a, a')$, $(b, b')$, and $(d, d')$:

\[
\begin{pmatrix}
(a) \\
(a') \\
(b) \\
(b') \\
(d) \\
(d')
\end{pmatrix} = \begin{pmatrix}
\vdots & 0 & \cdots & 1 & \cdots \\
\vdots & 1 & \cdots & 1 & \cdots \\
\vdots & 1 & 0 & \cdots & 0 & \cdots \\
\vdots & 0 & 1 & \cdots & 0 & \cdots \\
\vdots & 0 & \cdots & 1 & \cdots \\
\vdots & \cdots & j^{th\text{ coord.}} & \cdots & \cdots & k^{th\text{ coord.}} & \cdots 
\end{pmatrix}
\]

It is possible for $(b_j, b'_j)$ to be $(1, 1)$ or $(0, 0)$ when $(a_j, a'_j) = (0, 1)$, and $(b_k, b'_k)$ can be $(0, 1)$ or $(0, 0)$ when $(a_k, a'_k) = (1, 1)$. The $r$-face $(d, d')$ satisfies $(b, b') < (d, d') < (a, a')$ and has $n - 2$ coordinates which match corresponding coordinates of
\((a, a')\). Also, since there is at most one index \(l\) for which \(a'_l > b'_l\), \((b_j, b'_j)\) and \((b_k, b'_k)\) cannot both be \((0, 0)\), hence either the \(j^{th}\) or \(k^{th}\) coordinate of \((b, b')\) matches the corresponding coordinate of \((d, d')\), which is a contradiction, since the sequential replacement would have replaced \((a, a')\) with \((b, b')\).

The face \((a, a')\) is now known to have all \((1, 1)\) pairs to the left of all \((0, 1)\) pairs. It can be shown that removing \((a, a')\) from \(S^q\) causes the boundary set of \(S^q\) to decrease by at least \(r\) \((r - 1)\)-faces. Consider a boundary \((e, e')\) of \((a, a')\) which is obtained by changing the \((0, 1)\) pair at the \(j^{th}\) coordinate of \((a, a')\) to \((1, 1)\). Any other \(r\)-face \((c, c')\) distinct from \((a, a')\), satisfying \((e, e') \in \partial\{(c, c')\}\), must come from, at the \(k^{th}\) coordinate of \((e, e')\), changing either a \((1, 1)\) pair or a \((0, 0)\) pair to \((0, 1)\) (since \((e, e')\) is an \((r - 1)\)-face, \((c, c')\) must get another \((0, 1)\) pair in order to become an \(r\)-face). The case shown below is for \((e_k, e'_k) = (1, 1)\). Note that for all indices \(i \notin \{k, j\}, (a, a'_i) = (e, e'_i) = (c, c'_i)\).

\[
\begin{pmatrix}
   a \\
   a' \\
   e \\
   e' \\
   c \\
   c'
\end{pmatrix}
= 
\begin{pmatrix}
   \ldots & 1 & \ldots & 0 & \ldots \\
   \ldots & 1 & \ldots & 1 & \ldots \\
   \ldots & 1 & \ldots & 1 & \ldots \\
   \ldots & 0 & \ldots & 1 & \ldots \\
   \ldots & 1 & \ldots & 1 & \ldots \\
   \ldots & k & \ldots & j & \ldots
\end{pmatrix}
\]

Note that \(k \neq j\). Otherwise, if \((e_k, e'_k) = (1, 1)\), \(k = j\) contradicts the distinctness of \((a, a')\) and \((c, c')\); in fact, since all \((1, 1)\) pairs are to the left of all \((0, 1)\) pairs in \((a, a')\), \(k < j\) is obtained. Also, \((e_k, e'_k) = (0, 0)\) with \(k = j\) contradicts the construction of \((e, e')\) since \((e_j, e'_j) = (1, 1)\). If \((e_k, e'_k) = (0, 0)\), then \(c' > a'\). In either case, \((c, c') > (a, a')\); the \(r\) boundary elements of \(\partial S^q\) created in this manner are only in the boundary set of \((a, a')\) and in the boundary sets of \(r\)-faces larger than \((a, a')\). Since \((a, a')\) is the largest \(r\)-face in \(S^q\), at least \(r\) boundary elements are removed from \(\partial S^q\) when \((a, a')\) is removed from \(S^q\).

Finally, consider adding the face \((b, b')\) to \(S^q - \{(a, a')\}\). The case \(n = 1\) requires
$r = 0$ since otherwise $(a, a') = (b, b')$; hence there are no boundary elements to consider. It is not hard to check that the only case for $n = 2$ is

$$\begin{pmatrix} a \\ a' \end{pmatrix} = \begin{pmatrix} 10 \\ 11 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} b \\ b' \end{pmatrix} = \begin{pmatrix} 00 \\ 10 \end{pmatrix}.$$  

Since the boundary element $\begin{pmatrix} e \\ e' \end{pmatrix} = \begin{pmatrix} 00 \\ 00 \end{pmatrix} \in \partial\{(b, b')\}$ is also contained in the boundary of the $r$-face $\begin{pmatrix} 00 \\ 01 \end{pmatrix}$, which is smaller than $(b, b')$, adding $(b, b')$ to $S^g_+ - \{(a, a')\}$ adds at most $r = 1$ boundary elements to $\partial(S^g_+ - \{(a, a')\})$. In this case $r$ must be 1; the subcase $r = 0$ has no boundary elements to check, and the subcase $r = 2$ implies $(a, a') = (b, b')$, a contradiction. For the case where $n > 2$, if $r = 0$ there is nothing to check. If $r > 0$, at some coordinate $j$, $(b_j, b'_j) = (1, 1)$. Otherwise, if there are no $(1, 1)$ pairs in $(b, b')$, since every $(0, 1)$ pair of $(a, a')$ must then match $(0, 0)$ pairs of $(b, b')$, $r = 1$; this is because there can only be one index $i$ for which $b'_i < a'_i$. The $(0, 0)$ pairs and $(1, 1)$ pairs of $(a, a')$ must match $(0, 1)$ pairs of $(b, b')$ since matching a $(1, 1)$ pair of $(a, a')$ with a $(0, 0)$ pair of $(b, b')$ would give another index $i$ for which $b'_i < a'_i$, and by assumption there are no $(1, 1)$ pairs of $(b, b')$ to match with the $(0, 0)$ pairs of $(a, a')$. Hence the total number of $(0, 0)$ pairs and $(1, 1)$ pairs of $(a, a')$ is bounded above by the total number of $(0, 1)$ pairs of $(b, b')$ which is $r = 1$, giving $n \leq 2$, a contradiction.

It is now known that $(b, b')$ has at least one $(1, 1)$ pair, and $n > 2$ and $r > 0$ can be assumed; without loss of generality, let $(b_j, b'_j) = (1, 1)$. Let $(e, e')$ be the boundary of $(b, b')$ created by changing a $(0, 1)$ pair to a $(0, 0)$ pair at the $k$th coordinate. Then define $(c, c')$ from $(e, e')$ by changing the $(1, 1)$ pair to a $(0, 1)$ pair at the $j$th coordinate.

$$\begin{pmatrix} b \\ b' \end{pmatrix} = \begin{pmatrix} \cdots 1 \cdots \\ \cdots 1 \cdots \end{pmatrix}$$  

$$\begin{pmatrix} e \\ e' \end{pmatrix} = \begin{pmatrix} \cdots 1 \cdots \\ \cdots 1 \cdots \end{pmatrix}$$  

$$\begin{pmatrix} c \\ c' \end{pmatrix} = \begin{pmatrix} \cdots 0 \cdots \\ \cdots 1 \cdots \\ \cdots j \cdots \end{pmatrix}$$

21
Now \((e, e')\) is also in the boundary of \((c, c')\), which is smaller than \((b, b')\); hence \((e, e')\) is not added to \(\partial(S_r^2 - \{(a, a')\})\) when \((b, b')\) is added to \(S_r^2 - \{(a, a')\}\). Since such a boundary element is created for each \((0, 1)\) pair of \((b, b')\), at most \(r\) boundary elements are added to \(\partial(S_r^2 - \{(a, a')\})\) when \((b, b')\) is added to \(S_r^2 - \{(a, a')\}\).

At least \(r\) \((r - 1)\)-faces are removed from \(\partial S_r^2\) when \((a, a')\) is taken away from \(S_r^2\). At most \(r\) \((r - 1)\)-faces are added to \(\partial(S_r^2 - \{(a, a')\})\) when \((b, b')\) is added to \(S_r^2 - \{(a, a')\}\). The desired result is achieved; i.e., \(|\partial((S_r^2 - \{(a, a')\}) \cup \{(b, b')\})| \leq |\partial S_r^2|\). To further show that \(|\partial RS_r| \leq |\partial R^2|\) is a straightforward matter of iteration, as Lindström discusses in [4]. Let \(T = (S_r^2 - \{(a, a')\}) \cup \{(b, b')\}\). If \(T \neq RS_r\), let \((a, a')\) be the last \(r\)-face in \(T\) and let \((b, b')\) be the first \(r\)-face not in \(T\). \(T\) must satisfy the same properties as \(S_r^2\) after the sequential replacement step. If not, the sequential replacement step is able to replace faces of \(T\). Let the first such replacement be from \((x, x')\) to \((y, y')\), where \((x, x') \in T\) and \((y, y') \notin T\). Since \((b, b') < (y, y') < (x, x') < (a, a')\), \((x, x') \in S_r^2\) and \((y, y') \notin S_r^2\). Then the sequential replacement step would also have replaced \((x, x')\) to \((y, y')\) in \(S_r^2\). Hence \(R_lT = T\) for all \(l \in \{1, \ldots, n\}\), and the process of arbitrary replacement may be repeatedly with \(T\) in the place of \(S_r^2\) until the set \(RS_r\) is obtained. The final result below is obtained.

\[|\partial RS_r| \leq |\partial S_r|\]

Now \(R \partial S_r\) is an initial set with respect to the total order on \((r - 1)\)-faces, so if \(\partial RS_r\) is initial with respect to this order, it is clear that \(\partial RS_r \subseteq R \partial S_r\), which is precisely the statement of Theorem 1, the crucial inclusion. By the following lemma (proved in [4]), \(\partial RS_r\) is indeed initial, so Theorem 1 holds.

**Lemma 1.** If \(RS_r = S_r\), then \(R \partial S_r = \partial S_r\).

The proof of this lemma is included in the Appendix.
3.3 Proof of the Corollary to Theorem 1

Proof of Corollary 1. To prove the first inequality of the corollary, \(|\partial^p R S_r| \leq |\partial^p S_r|\), it is sufficient to show

\[
\partial^p R S_r \subseteq R \partial^p S_r, \quad p = 1, \ldots, r.
\]  

(6)

The case for \(p = 1\) is the statement of Theorem 1. By induction, suppose \(\partial^{p-1} R S_r \subseteq R \partial^{p-1} S_r\) holds. Since both sets consist of faces in the \(n\)-cube, applying \(\partial\) to both sides yields

\[
\partial^p R S_r \subseteq \partial R \partial^{p-1} S_r,
\]  

(7)

and applying Theorem 1 to the right side of (7) yields the desired result in (6). Since \(|R \partial^p S_r| = |\partial^p S_r|\), the first inequality of Corollary 1 follows.

To prove the second inequality of the corollary, \(|\partial^{-p} S_r| \leq |\partial^{-p} R S_r|\), it is sufficient to show by induction

\[
R \partial^{-p} S_r \subseteq \partial^{-p} R S_r, \quad p = 1, \ldots, n-r.
\]

For the case \(p = 1\), recall that by definition of the boundary operator

\[
\partial^{-1} \partial S_r = S_r, \quad \partial \partial^{-1} S_r \subseteq S_r.
\]  

(8)

If \(S_r\) is replaced by \(\partial^{-1} S_r\) in the theorem, applying (8) and then \(\partial^{-1}\) yields

\[
\partial R \partial^{-1} S_r \subseteq R \partial \partial^{-1} S_r \subseteq RS_r,
\]

\[
R \partial^{-1} S_r \subseteq \partial^{-1} R S_r.
\]  

(9)

By induction, suppose \(R \partial^{-(p-1)} S_r \subseteq \partial^{-(p-1)} R S_r\) holds. Then replacing \(S_r\) with \(\partial^{-(p-1)} S_r\) in (9) and applying the induction for \((p - 1)\) yields

\[
R \partial^{-p} S_r = R \partial^{-1} \partial^{-(p-1)} S_r \subseteq \partial^{-1} R \partial^{-(p-1)} S_r \subseteq \partial^{-1} \partial^{-(p-1)} R S_r = \partial^{-p} R S_r.
\]

The second inequality of Corollary 1 follows from this inclusion, which completes the proof.
Example 7. Consider the set $S_2$ of 2-faces which lie in the 3-cube, as shown in Figure 7(a). $S_2$ consists of the faces $w_{03}$ and $w_{47}$. The second boundary of $S_2$, $\partial^2 S_2$, is shown in Figure 7(b); i.e., all eight vertices of the 3-cube. After the replacement operator $R$ acts on $S_2$, the result appears as $RS_2$, in Figure 7(c). The number of vertices in the second repeated boundary of $RS_2$, however, is only six, as shown in Figure 7(d). This agrees with the Corollary to Theorem 1, which states for $p = 2$ that $|\partial^2 RS_2| \leq |\partial^2 S_2|$.

Figure 7: A set of 2-faces, $S_2$, appears in (a), and the vertices of the boundary $\partial^2 S_2$ appear in (b). After the replacement operator is applied to $S_2$, $RS_2$ is depicted in (c), with its smaller number of boundary vertices $\partial^2 RS_2$ in (d).

Now it has been shown that the minimum (maximum) number of faces in the boundary (coboundary) of the set $S_r$ of $r$-faces of a cubical complex $C$ is bounded below (above) by that in the case where $S_r$ is an initial set of $r$-faces, further attention is restricted to this case, $S_r = RS_r$. After reviewing the derivation of the formula for the optimal number of faces in the boundary or coboundary of a set of $r$-faces of a simplicial complex, the formula for the exact number of faces in the boundary or coboundary of an initial set of $r$-faces will be obtained.
4 The Optimal Number of Faces for Simplicial Complexes

The derivation of a closed formula for the optimal number of faces in cubical complexes requires a previous result for the optimal number of faces in simplicial complexes shown by J. B. Kruskal in [3]. What follows here is a summary of the necessary results from Kruskal’s work in order to derive the formula for cubical complexes.

Definition. A simplicial (or binary) complex $\Delta$ is a finite collection of finite sets or faces which satisfy the property that if $F \in \Delta$ is a set of the simplicial complex, then all subsets $G \subseteq F$ must also be in $\Delta$.

A set of a simplicial complex is also referred to as a face. A standard representation of simplicial complexes is obtained by representing the faces as binary words of length $n$; subfaces are determined by binary inclusion, with the empty face represented as the binary word with $n$ 0’s. The weight of a binary word is the number of 1’s that appear in the word. A total order is established on the faces by inheriting the total order on the binary words.

Example 8. Simplicial complexes are best viewed as vertices, edges, triangles, tetrahedrons, and higher dimensional structures. Cubical complexes are divided into those that can be embedded in $n$-cubes and those that cannot, but all simplicial complexes can be viewed as a finite, arbitrary collection of vertices in Euclidean space $\mathbb{R}^n$ with the structure of edges, triangles, etc., superimposed. A face of a simplicial complex is denoted by the vertices that appear in it. The simplicial complex, $\Delta$, in Figure 8 consists of the triangle $ABC$, the edge $BD$, the tetrahedron $DEFG$, and all subfaces of these three faces. The complex can be written in terms of its vertices: $\Delta = \{\emptyset, A, B, C, D, E, F, G, AB, AC, BC, BD, DE, DF, DG, EF, EG, FG, ABC, DEF, DEG, DFG, EFG, DEFG\}$. If the complex is written in terms of the faces that generate it, then $\Delta = \{DEFG, ABC, BD\}$. To convert the simplicial complex
into a binary complex, represent $A$ through $G$ as the least significant bit through the most significant bit, respectively, of a 7-bit binary word; i.e., $A = 0000001$, $B = 0000010$, and so forth. Then in terms of binary word generators, the binary complex can be written as $\Delta = \langle 1111000, 0000111, 0001010 \rangle$.

![Diagram](image)

Figure 8: The simplicial complex consists of the tetrahedron $DEFG$, the triangle $ABC$, the edge $BD$, and all subfaces of these faces.

Before the results are stated, some notation must be defined. As in [3] for any positive integer $m$ define the $r$-canonical representation

$$m = \binom{m_1}{r} + \binom{m_2}{r-1} + \ldots + \binom{m_k}{r-k+1},$$

where $m_i$ for $1 \leq i \leq k$ is chosen as large as possible such that

$$\binom{m_1}{r} + \ldots + \binom{m_i}{r-i+1} \leq m,$$

until equality is obtained at $i = k$. Kruskal shows that this representation is unique and that the following relationships hold:

$$m_1 > m_2 > \ldots > m_k \geq r - k + 1 \geq 1.$$

Define for any sequence of positive integers $m_1, \ldots, m_k$

$$[m_1, \ldots, m_k]_r = \binom{m_1}{r} + \binom{m_2}{r-1} + \ldots + \binom{m_k}{r-k+1}.$$
Then if \( m = [m_1, \ldots, m_k]_r \) is the \( r \)-canonical representation of \( m \), Kruskal defines the fractional pseudopower \( m^{(s/r)} \) to be
\[
m^{(s/r)} = [m_1, \ldots, m_k]_s,
\]
with \( 0^{(s/r)} = 0 \). The background is complete for the next theorem.

**Kruskal’s Theorem.** If a simplicial complex \( \Delta \) has exactly \( m \) words of weight \( r \), and if \( s > r(s < r) \), then the maximum (minimum) number of integers of weight \( s \) that \( \Delta \) can have is \( m^{(s/r)} \).

This theorem provides the optimization formula for simplicial complexes and is analogous to the optimization formula for cubical complexes which will be derived in the next section. The proof of this theorem, which appears in [3], follows with some work by the application of the next two lemmas.

**Lemma 2.** Let \( m_1, \ldots, m_k \) be nonnegative integers. Then the number of integers of weight \( r \), which are less than \( 2^{m_1} + \ldots + 2^{m_k} \), is \([m_1, \ldots, m_k]_r\).

If \( S \) is a set of binary words of weight \( r \), define the set \( r(S) \) of related words as the set of all words \( x \) such that either \( x \subseteq y \) for some \( y \in S \) or \( y \in S \) for each \( y \subseteq x \). This provides the setting for the next lemma.

**Lemma 3.** Let \( S \) be the \( m \) first nonnegative integers of weight \( r \). Then the number of integers of weight \( s \) in \( r(S) \) is \( m^{(s/r)} \), and \( r(S) \) is the set of all non-negative integers which are less than \( 2^{m_1} + \ldots + 2^{m_k} \), if \( m = [m_1, \ldots, m_k] \), is the \( r \)-canonical representation of \( m \).

The proof of Lemmas 2 and 3 are given in Appendix A; these proofs demonstrate tools that are used to prove the analogous computational result for cubical complexes. Lemmas 2 and 3 lead to a proof of Kruskal’s theorem, but this proof is omitted as it has less relevance to the proof of the analogous computational result for cubical complexes.
5 The Optimal Number of Faces for Cubical Complexes

As discussed in the previous section, the definition of the fractional pseudopower is crucial to the development of a computational formula for the optimal number of faces in a simplicial complex. This definition allows the counting of the number of binary words of weight $r$ that are less than a fixed binary word. For cubical complexes, it is useful to define a similar formula to count the number of faces of dimension $r$ which are less than a fixed vertex (recalling that a vertex is a 0-dimensional face). To this end, the following function defined by Kruskal in [2] is required:

$$g(r, i, m) = \sum_{v=0}^{r} \binom{m}{r-v} \binom{i-1}{v} 2^{m-(r-v)}. \quad (10)$$

Kruskal used this function in an attempt at defining the optimality conditions for cubical complexes, which are correct for a relatively small number of cases. Lindström demonstrates in [4] that (10) is also given as

$$g(r, i, m) = \sum_{v=0}^{m} \binom{m}{v} \binom{v+i-1}{r}. \quad (11)$$

Lindström takes this function and develops the corresponding pseudopower expression for cubical complexes. Analogously to the result for fractional pseudopowers arising from Pascal's triangle,

$$g(r, i, m) + g(r, i+1, m) = g(r, i, m + 1). \quad (11)$$

Given an integer $m > 0$, determine $m_1, m_2, \ldots, m_k$ such that

$$m \geq g(r, 1, m_1) + \ldots + g(r, k, m_k) = m_{r/r}, \quad (12)$$

where first $m_1$ is chosen to be as large as possible such that $m \geq g(r, 1, m_1)$, then $m_2$ is chosen to be as large as possible such that $m \geq g(r, 1, m_1) + g(r, 2, m_2)$, and
so forth. Equality is not always obtained, but the resulting sum in (12) is defined to be $m_{(r/r)}$, and it follows from (11) that

$$m_1 > m_2 > \ldots > m_k \geq r - k + 1.$$  

(13)

For the sum defined in (12) for $m > 0$, define the lower semipower, $m_{(s/r)}$, by

$$m_{(s/r)} = g(s, 1, m_1) + \ldots + g(s, k, m_k).$$  

(14)

The lower semipower is defined in analogy with Kruskal's fractional pseudopower, which will also be referred to as the upper semipower. Now Lindström's main result, which appears as Theorem 3 in [4], can be stated as a computational formula for the optimal number of faces in cubical complexes involving upper and lower semipowers.

**Theorem 2.** If a cubical complex $C$ has $m$ faces of dimension $r$, and if $s > r$ ($s < r$), then the maximum (minimum) number of faces of dimension $s$ that it can have is

$$m_{(s/r)} + (m - m_{(r/r)}^{(s/r)}).$$

Theorem 2 follows from two lemmas which appear as Lemma 4 and Lemma 5 in [4], which Lindström gives without proof. Lemmas 4 and 5 are analogous to Lemmas 2 and 3 for simplicial complexes, and their proofs are similar. These lemmas are stated below with proof, and afterward the proof of Theorem 2 is given (of which Lindström gives a brief version in [4]).

**Lemma 4.** Let $m_1 > m_2 > \ldots > m_k$ be nonnegative integers. Then the number of $r$-faces $w_{ij}$, with $j < 2^{m_1} + \ldots + 2^{m_k}$, is

$$g(r, 1, m_1) + \ldots + g(r, k, m_k).$$

**Proof of Lemma 4.** It is convenient to first partition $S$ into $k$ disjoint sets that are each counted by the function given in (10). Let $S$ be the set of $r$-faces $w_{ij}$ with

</table>

\[ j < 2^{m_1} + \ldots + 2^{m_k}. \] For \(l \in \{1, \ldots, k\}\), define \(S_l\) to be the set of \(r\)-faces \(w_{ij}\) of \(S\) for which \(j\) has a 1 in the \(2^{m_1}, \ldots, 2^{m_{l-1}}\) positions and a 0 in the \(2^{m_l}\) position. It can be shown that
\[ S = S_1 \cup \ldots \cup S_k, \tag{15} \]
and furthermore that the right-hand side of (15) is a disjoint union.

To show containment in the forward direction, let \(w_{ij}\) be an \(r\)-face of \(S\). Then \(j < 2^{m_1} + \ldots + 2^{m_k}\); hence \(j\) must differ from \(2^{m_1} + \ldots + 2^{m_k}\) at some first position \(2^{m_l}\), and \(j \in S_l\) by definition. It is easy to see that \(l \in \{1, \ldots, k\}\). The reverse containment follows from the definition of the sets \(S_1, \ldots, S_k\). To show that the right-hand side of (15) is a disjoint union, let \(p, q \in \{1, \ldots, k\}\). Without loss of generality suppose \(p > q\). Let \(w_{ij}\) and \(w_{uv}\) be members of \(S_p\) and \(S_q\), respectively. Then \(j\) has a 1 at the \(2^{m_q}\) position and \(v\) has a 0 at the \(2^{m_q}\) position; hence \(w_{ij} \neq w_{uv}\) and \(S_p \cap S_q = \emptyset\) for all \(p \neq q\).

Now fix \(l \in \{1, \ldots, k\}\) and consider \(|S_l|\). Let \(w_{ij}\) be an arbitrary member of \(S_l\). Then \(j\) has 1's in the \(l - 1\) positions \(2^{m_1}, \ldots, 2^{m_{l-1}}\), a 0 in the \(2^{m_l}\) position, and either a 1 or a 0 in each of \(m_l\) positions to the right of the \(2^{m_l}\) position. Thus \(w_{ij}\)
can have a (0, 1) or a (1, 1) pair in each of the $m_1, \ldots, m_{l-1}$ coordinates, (0, 0) pairs in the $m_l$ coordinate and all the other coordinates to the left of the $m_l$ coordinate, and a (0, 0), (0, 1) or a (1, 1) pair in each of the coordinates to the right of the $m_l$ coordinate. Since the dimension of $w_{ij}$ is $r$, $w_{ij}$ must have $r$ (0, 1) pairs; let $v$ be the number of (0, 1) pairs of $w_{ij}$ which occur to the left of the $m_l$ coordinate. There are $l - 1$ coordinates in which to place these $v$ pairs, leaving the remaining coordinates fixed at (1, 1). Since $r - v$ of the (0, 1) pairs occur to the right of the $m_l$ coordinate, there are $m_l$ positions in which to place these $r - v$ pairs, leaving a choice between (0, 0) and (1, 1) for the remaining $m_l - (r - v)$ coordinates. Since $v$ may range from 0 to $r$, the following formula for $|S_i|$ arises:

$$|S_i| = \sum_{v=0}^{r} \binom{m_l}{r-v} \binom{l-1}{v} 2^{m_l-(r-v)} = g(r, l, m_l).$$

(16)

The result follows by letting $i$ range from 1 to $k$, completing the proof of Lemma 1.

As in the analogous proof for simplicial complexes, the background for the next lemma is set by defining, for a set $S$ of $r$-faces, $r(S)$ to be the set of faces related to $S$; that is, $r(S)$ is the set of faces $w_{uv}$ such that $w_{uv}$ is either a subface of some $r$-face $w_{ij}$ in $S$, or all the $r$-faces $w_{ij}$ which are subfaces of $w_{uv}$ are contained in $S$. This definition can also be written as

$$r(S) = \bigcup_{p=-\infty}^{r} \partial^p(S).$$

Note that when $p > r$ that $\partial^p(S) = \emptyset$. Also, $r(S)$ is a finite set since a single face of dimension $s > r$ contains $2^{s-r}$ subfaces of dimension $r$; in other words, there exists some positive integer $B$ such that

$$\bigcup_{p=-\infty}^{r} \partial^p(S) = \bigcup_{p=-B}^{r} \partial^p(S).$$

**Lemma 5.** Assume that $m = m_{(r/r)}$ and let $S$ be the $m$ first $r$-cubes $w_{ij}$ in the total ordering of cubes. Then the number of $s$-faces of $r(S)$ is $m_{(s/r)}$, and $r(S)$ is the set
of all faces \(w_{uv}\) such that \(v < 2^{m_1} + \ldots + 2^{m_k}\), if \(m \geq g(r, 1, m_1) + \ldots + g(r, k, m_k) = m_{(r/r)}\) under the conditions of (13).

**Proof of Lemma 5.** Analogously to the proof for simplicial complexes, it is useful to first prove the following set equality:

\[
r(S_r) = \{w_{uv} : v < 2^{m_1} + \ldots + 2^{m_k}\}.
\]  

(17)

For the forward containment of (17), let \(w_{uv} \in r(S_r)\), and let \(s\) be the dimension of \(w_{uv}\). Two cases arise.

1. If \(s \leq r\), then \(w_{ij}\) is in the \((r - s)\)th boundary of an \(r\)-face \(w_{ij} \in S_r\), and \(w_{uv}\) is created from \(w_{ij}\) by changing \((0,1)\) pairs to \((0,0)\) or \((1,1)\) pairs; in any event, \(v \leq j\), and since \(j < 2^{m_1} + \ldots + 2^{m_k}\), containment holds.

2. If \(s > r\), then \(S_r\) must contain the \(2^{s-r}\) \(r\)-faces in the \((s-r)\)th coboundary of \(w_{uv}\). Suppose to the contrary that \(v \geq 2^{m_1} + \ldots + 2^{m_k}\). Then by changing \((s-r)\) of the \((0,1)\) pairs of \(w_{uv}\) to \((1,1)\) pairs, the \(r\)-face \(w_{ij}\) for some binary word \(i\) is formed; by assumption this \(r\)-face must be in \(S_r\), but \(v \geq 2^{m_1} + \ldots + 2^{m_k}\) contradicts the construction of \(S_r\).

In either case, with Lemma 4 the forward containment follows.

For the reverse containment of (17), let \(w_{uv}\) be an \(s\)-face which satisfies \(v < 2^{m_1} + \ldots + 2^{m_k}\). Two cases arise.

1. If \(s \leq r\), let \(m_l\) be the first coordinate of \(w_{uv}\) for which \(v\) has a 0; thus \(v\) has 1’s in the \(2^{m_1}, \ldots 2^{m_{l-1}}\) positions. By (13), there are at least \(r - l + 1\) positions after the \(2^{m_l}\) position, or at least \(r\) total coordinates where either a \((0,1)\) pair exists in \(w_{uv}\), or a \((0,0)\) or \((1,1)\) pair of \(w_{uv}\) can be changed to \((0,1)\) to construct an \(r\)-face \(w_{ij}\) such that \(w_{ij} \in \partial^{s-r}(\{w_{ij}\})\) and \(j < 2^{m_1} + \ldots + 2^{m_k}\). By (16) and Lemma 4, the containment holds.
2. If $s > r$, it is sufficient to show that $\partial^{s-r}(\{w_{uv}\}) \subseteq S_r$. The $(s-r)$th boundary of $w_{uv}$ is created by choosing $(s-r)$ of the $(0,1)$ pairs of $w_{uv}$ and constructing the $r$-face $w_{ij}$ changing these pairs individually to either $(0,0)$ or $(1,1)$. In any event, $j \leq v$; by Lemma 4 $w_{ij} \in S_r$, and by (16) the containment holds. The equality in (17) follows from these containments.

From the previous equality, the number of $s$-faces in $r(S)$ is the same as the number of $s$ faces $w_{uv}$ which satisfy $v < 2^{m_1} + \ldots + 2^{m_k}$. By Lemma 4, this is just $g(s,1,m_1) + \ldots + g(s,k,m_k)$; but this is $m_{(s/r)}$ by (14). This completes the proof of Lemma 5.

Proof of Theorem 2. Let $S_r$ be the $r$-faces of the cubical complex $C$, with $m = |S_r|$. Corollary 1 to Theorem 1 allows the assumption that $S_r$ is an initial set of $r$-faces. If $s > r$, the set $S_r$ has at most as many $s$-faces in its $(s-r)$th coboundary as does the set $RS_r$; hence the possible number of $s$-faces in $C$ is maximized when $S_r = RS_r$. If $s < r$, the set $S_r$ has at least as many $s$-faces in its $(r-s)$th boundary as does the set $RS_r$; hence the possible number of $s$-faces in $C$ is minimized when $S_r = RS_r$.

If $m = m_{(r/r)}$, Theorem 2 follows from Lemmas 4 and 5. If $s < r$, by definition of cubical complexes, $C$ contains all of the faces of $r(S_r)$ that have dimension less than $r$. If $s > r$, $C$ contains a subset (possibly all) of the $s$-faces of $r(S_r)$. In either case, the optimal number of $s$-faces in $C$ is $m_{(s/r)}$.

Next assume that $m > m_{(r/r)} = g(r,1,m_1) + \ldots + g(r,k,m_k)$ and let $M = 2^{m_1} + \ldots + 2^{m_k}$. Then $S_r$ contains $m_{(r/r)}$ faces $w_{ij}$ with $j < M$ and $m - m_{(r/r)}$ faces $w_{iM}$, by Lemma 4. Let $w_{uM}$ be an arbitrary $s$-face; $w_{uM} \in r(S_r)$ if and only if $w_{uM}$ is a subface of some $r$-face $w_{iM} \in S_r$ or every $r$-face $w_{iM}$ in the boundary of $w_{uM}$ is in $S_r$. This follows by the definition of $r(S_r)$ and the observation that if $s > r$, all the $r$-subfaces $w_{ij}$ for which $j \neq M$ satisfy $j < M$ and $w_{ij} \in S_r$.

Since $M$ is fixed, it is useful to look at the complements $M - u$ and $M - i$ for an $s$-face and an $r$-face, respectively. Note that $M - u$ is a binary word of weight.
s, since \( w_{uM} \) has \( s (0,1) \) pairs. Similarly, \( M - i \) is a binary word of weight \( r \). If \( s > r \), an \( r \)-face \( w_{iM} \) is contained in the boundary of an \( s \)-face \( w_{uM} \) if and only if \( M - i \subset M - u \). Couching the previous bijection in terms of binary words, \( w_{uM} \in r(S_r) \) if and only if \( M - u \subset M - i \) for some \( r \)-face \( w_{iM} \), or every \( r \)-face \( w_{iM} \) is in \( S_r \) when \( M - i \subset M - u \). By the total ordering on cubical faces, the \( m - m_{(r/r)} \) faces \( w_{iM} \) in \( S_r \) correspond to the \( m - m_{(r/r)} \) first binary words \( M - i \) of weight \( r \). By Lemma 3, the optimal number of binary words of weight \( s \) that a binary complex with the \( m - m_{(r/r)} \) first binary words of weight \( r \) can have is \( (m - m_{(r/r)})^{(s/r)} \). By the bijection above, these binary words of weight \( s \) correspond to the \( (m - m_{(r/r)})^{(s/r)} \) \( s \)-faces \( w_{uM} \) in \( r(S_r) \). Thus the set \( r(S_r) \) consists of \( m_{(s/r)} \) \( s \)-faces \( w_{uv} \) with \( v < 2^{m_1} + \ldots + 2^{m_k} \) and \( (m - m_{(r/r)})^{(s/r)} \) \( s \)-faces \( w_{uM} \). This completes the proof of Theorem 2.

6 Characterization of \( f \)-vectors of Cubical Complexes

Theorem 2 leads to a characterization of cubical complexes in terms of the allowable number of faces of a given dimension. If a cubical complex \( C \) has \( m \) faces of dimension \( r < s \), then it cannot have more than \( m_{(s/r)} + (m - m_{(r/r)})^{(s/r)} \) faces of dimension \( s \); of course a similar statement can be made for the case \( r > s \). If the information about the number of faces of a given dimension of a candidate cubical complex \( C \) is available, application of the theorem determines whether or not \( C \) is a legal cubical complex. This information about the cubical complex is called the \( f \)-vector of the complex.

**Definition.** Let \( C \) be a cubical complex and let \( f = (f_0, f_1, \ldots, f_d) \) be a \((d+1)\)-tuple of positive integers. Then \( f \) is the \( f \)-vector of \( C \) if and only if \( C \) has \( f_i \) faces of dimension \( i \) (the \( f \)-vector of the empty complex is the empty tuple). Furthermore, the dimension of the complex is \( d \) (or \(-1\) for the empty complex).
The $f$-vector is the necessary tool for storing the information about the number of faces of each dimension of the cubical complex. For example, Theorem 2 can be applied to an $f$-vector $f$ of a cubical complex $C$, by choosing two nonnegative integers $0 \leq i < j \leq d$, and verifying $f_j \leq (f_i)_{(s/r)} + (f_i - (f_i)_{(r/s)})^{(s/r)}$. This leads to the next theorem.

**Theorem 3.** Let $f = (f_0, f_1, \ldots, f_d)$ be a $(d + 1)$-tuple of positive integers. Then $f$ is the $f$-vector of a cubical complex $C$ if and only if

$$f_{i+1} \leq (f_i)_{(i+1/i)} + (f_i - (f_i)_{(i/i)})^{(i+1/i)}, \quad i = 0, \ldots, d - 1. \quad (18)$$

</tbody>
</table>

**Proof of Theorem 3.** The forward direction follows by repeated application of Theorem 2. For the reverse direction, let $f = (f_0, f_1, \ldots, f_d)$ be a $(d + 1)$-tuple of positive integers which satisfies (18). It can be shown by construction that there exists a cubical complex $C$ that has $f$ as an $f$-vector. Let $S_i$ be the first $f_i$ $i$-faces in the total ordering, for $i = 0, \ldots, d$. Initialize the construction of $C$ by letting $C = S_0$, the first $f_0$ 0-faces (vertices) of the total ordering. As seen in the proof of Theorem 2, $r(S_0)$ contains the $((f_0)_{(1/0)} + (f_0 - (f_0)_{(1/0)})^{(1/0)})$ first 1-faces in the total order. By assumption, this is an upper bound for $f_1$; by letting $C = C \cup S_1$, $C$ is still a cubical complex since $S_1 \subseteq r(S_0)$ (the boundary of $S_1$ is also in $C$). Continue this process similarly for each $0 \leq i \leq d$ to obtain the cubical complex $C = S_1 \cup \ldots \cup S_d$ for which $\partial S_d \subseteq S_{d-1}, \ldots, \partial S_1 \subseteq S_0$. This completes the proof of Theorem 3.
7 \textit{f-Vectors of Arbitrary Cubical Complexes}

The proofs of Theorems 2 and 3 completely ignore the case of cubical complexes which do not lie in cubes. The examples here show that Theorem 3 does not hold for arbitrary cubical complexes, leaving open the question of characterization of \textit{f}-vectors of arbitrary cubical complexes.

\textbf{Definition.} \textit{A cubical complex C (not necessarily embeddable in a cube) is a finite collection of finite sets which satisfy the following properties:}

1. If $F \in C$ and $G$ is a subset of $F$, then $G \in C$.

2. If $F$ is a member of $C$, then $F$ is a cube of finite dimension.

A cubical complex that contains a triangle or some other odd-sided polygon has a closed path of odd length and is not embeddable in a cube (recall that closed paths in cubes must have even length). For similar reasons, a cubical complex which contains three squares forming a triangle, i.e., the cross product of a triangle and an edge, is not embeddable in a cube. Furthermore, Theorem 3 does not hold for these complexes, as is illustrated in the final example.

\textbf{Example 9.} The cubical complex $C$ in Figure 9 can be viewed as the cross product of a triangle and a line and has the associated \textit{f}-vector $(6, 9, 3)$. Theorem 3 fails for this \textit{f}-vector in two places. According to the theorem $C$ must have at least 7 0-faces to have 9 1-faces, and $C$ can have at most 2 2-faces given that it has 6 0-faces.

![Figure 9: Theorem 3 fails for this cubical complex.](image-url)
Appendix: Proofs of Technical Lemmas

Lemma 1. If $RS_r = S_r$, then $R\partial S_r = \partial S_r$.

Proof of Lemma 1. It must be shown that if $S_r$ is an initial set of $r$-faces, then the boundary set $\partial S_r$ must be an initial set of $(r - 1)$ faces. Let $(f, f') \in \partial S_r$ be an $(r - 1)$-face. To prove the lemma it is sufficient to show that whenever $(e, e')$ is an $(r - 1)$-face and $(e, e') < (f, f')$, then $(e, e') \in \partial S_r$.

If $(f, f') \in \partial S_r$, then there must be an $r$-face $(h, h') \in S_r$ such that $(f, f') \in \partial\{h, h'\}$. From this point there are two cases, $e' = h'$ and $e' < h'$.

Case 1. Assume $e' = h'$. For $n < 3$ there are a small number of cases which are easily verified. The total order on faces forces $e' = f' = h'$. In this case, $(f, f')$ cannot have been created from $(h, h')$ by changing a $(0, 1)$ pair to a $(0, 0)$ pair, since this would violate $f' = h'$. Hence $f = h$ except for a single index $j$ for which $f_j = 1$ and $h_j = 0$. The total order on faces requires $e > f$, so let $k$ be the index for which $e_i = f_i$ for all indices $i$ less than $k$ and $e_k > f_k$. Note that $e'_k = f'_k = 1$ since $e' = f'$. Also, $j \neq k$ since $f_j = 1$ and $f_k = 0$. If $j < k$ the situation below is obtained.

$$
\begin{pmatrix}
  h \\
  h' \\
  f \\
  f'
\end{pmatrix} =
\begin{pmatrix}
  \ldots & 0 & \ldots & 0 \\
  \ldots & 1 & \ldots & \ldots \\
  \ldots & 1 & \ldots & \ldots \\
  \ldots & 1 & \ldots & \ldots \\
  \ldots & \ldots & \ldots & k
\end{pmatrix}
\begin{pmatrix}
  e \\
  e'
\end{pmatrix}
$$

Construct the $r$-face $(g, g')$ by letting $(g_i, g'_i) = (e_i, e'_i)$ for all indices $i$ except for $i = j$, for which $(g_j, g'_j) = (0, 1)$.

$$
\begin{pmatrix}
  g \\
  g'
\end{pmatrix} =
\begin{pmatrix}
  \ldots & 0 & \ldots & 1 \\
  \ldots & 1 & \ldots & \ldots \\
  \ldots & \ldots & \ldots & k
\end{pmatrix}
$$

This gives $g > h$ and $(g, g') < (h, h')$. But if $S_r$ is an initial set of $r$-faces and $(h, h') \in S_r$, certainly $(g, g') \in S_r$, and since $(e, e') \in \partial\{(g, g')\}$, by definition $(e, e') \in \partial S_r$. 37
If \( j > k \) the situation below is obtained.

\[
\begin{pmatrix}
  h \\
  h' \\
  f \\
  f' \\
  e \\
  e'
\end{pmatrix}
=
\begin{pmatrix}
  \ldots 0 0 \ldots \\
  \ldots 1 1 \ldots \\
  \ldots 0 1 \ldots \\
  \ldots 1 1 \ldots \\
  \ldots 1 \ldots e_j \\
  \ldots 1 \ldots e_k
\end{pmatrix}
\]

If there is an index \( l > k \) for which \( e_l = 1 \), construct \((g, g')\) by letting \((g_i, g'_i) = (e_i, e'_i)\) for all indices \( i \) except \( i = l \) and let \((g_l, g'_l) = (0, 1)\). Then \( g > h \), hence \((g, g') < (h, h') \Rightarrow (g, g') \in S_r\). Thus \((e, e') \in \partial S_r\).

If for all indices \( i > k \) we have \( e_i = 0 \), it is necessary to see that \( e \) and \( f \) have the same number of 1's. This follows from seeing that \( e \) and \( f \) have the same number of 0's. Both \((e, e')\) and \((f, f')\) are \((r - 1)\)-faces, and \( e' = f' \). Let \( a \) be the number of 0's in \( e' \) (or \( j' \)). Then both \( e \) and \( f \) have 0's in the corresponding coordinates since \((1, 0)\) is not a legal pair. The only other 0's of \( e \) or \( f \) match with 1's in \( e' \) or \( f' \) respectively, giving \( r - 1 \) such \((0, 1)\) pairs in \((e, e')\) (or \((f, f')\)) and \( a + r - 1 \) total 0's in \( e \) (or \( f \)). Thus \( e \) and \( f \) have the same number of 0's and the same number of 1's.

Since \( e_i = f_i \) holds for all \( 1 \leq i < k \), and \( e_i = 0 \) holds for all \( i > k \), as \( e \) and \( f \) have the same number of 1's \( h_i = f_i = e_i = 0 \) is obtained for all \( i \in \{k + 1, \ldots, j - 1, j + 1, \ldots, n\} \). It is easy to see now that \((e, e') \in \partial\{(h, h')\}\) by changing the \( k \)th coordinate of \((h, h')\) from \((0, 1)\) to \((1, 1)\); hence \((e, e') \in \partial S_r\).

**Case 2.** Assume that \( e' < h' \). If there is an index \( j \) such that \((e_j, e'_j) = (1, 1)\), construct \((g, g')\) by letting \((g_i, g'_i) = (e_i, e'_i)\) for all indices \( i \) except \( i = j \), and let \((g_j, g'_j) = (0, 1)\). Since \( g' = e' < h' \), \((g, g') < (h, h')\) and \((e, e') \in \partial\{(g, g')\}\) give \((e, e') \in \partial S_r\), because \( S_r \) is an initial set of \( r \)-faces which contains \((h, h') > (g, g')\).

Otherwise, suppose that \((e_i, e'_i) \in \{(0, 1), (0, 0)\}\) for all indices \( i \). Since \( e' < h' \), let \( j \) be the index for which \( e'_j = h'_j \) for all indices \( i < j \) and \( e'_j < h'_j \). If \((e_k, e'_k) = (0, 0)\)
for some $k > j$, the situation below arises.

$$
\begin{pmatrix}
  h \\
  h' \\
  e \\
  e'
\end{pmatrix} =
\begin{pmatrix}
  \ldots h_j \ldots h_k \ldots \\
  \ldots 1 \ldots h'_k \ldots \\
  \ldots 0 \ldots 0 \ldots \\
  \ldots 0 \ldots 0 \\
  \quad \quad \quad \quad \ldots j \ldots k 
\end{pmatrix}
$$

Let $(g_i, g'_i) = (e_i, e'_i)$ for all indices $i$ except $i = k$, and let $(g_k, g'_k) = (0, 1)$. Then $g' < h'$ and $(g, g') < (h, h')$; hence, $(e, e') \in \partial S_r$.

Otherwise, $(e_i, e'_i) = (0, 1)$ for all indices $i > j$. Then

$$(e, e') = (0 \ldots 0, h'_1 \ldots h'_{j-1} 01 \ldots 1).$$

The face $(e, e')$ has dimension $r - 1$ and hence $r - 1$ coordinates $(0, 1)$. For each index $i > j$, $(e_i, e'_i) = (0, 1)$, giving $n - j$ of these $(0, 1)$ coordinates. The remainder must come from $(r - 1) - (n - j)$ of the coordinates $(e_i, e'_i)$ where $1 \leq i < j$. Thus $h'$ has $h'_i = 1$ for $(r - 1) - (n - j)$ of the indices $1 \leq i < j$ and $h'_i = 0$ for the rest of those indices. But $(h, h')$ has dimension $r$, and must satisfy $(h_i, h'_i) = (0, 1)$ (and in particular, $h'_i = 1$) for $r$ indices $i$ with $1 \leq i \leq n$. Of these, at most $(r - 1) - (n - j)$ come from indices $i$ for which $1 \leq i < j$. There are $(n - j + 1)$ other indices $i$ with $j \leq i \leq n$, which gives $(r - 1) - (n - j) + (n - j + 1) = r$; hence all indices $i$ for which $h'_i = 1$ force the equalities $h_i = 0$, and $(h, h') = (0 \ldots 0, h'_1 \ldots h'_{j-1} 1 \ldots 1)$. Thus $(e, e') \in \partial\{(h, h')\}$, $(e, e') \in \partial S_r$, and the lemma is proved.

**Lemma 2.** Let $m_1, \ldots, m_k$ be nonnegative integers. Then the number of integers of weight $r$, which are less than $2^{m_1} + \ldots + 2^{m_k}$, is $[m_1, \ldots, m_k]_r$.

**Proof of Lemma 2.** Let $S$ be the set of binary words of weight $r$ which are less than $2^{m_1} + \ldots + 2^{m_k}$. Let $S_i$, for each $i \in \{1, \ldots, k\}$, be the set of binary words of $S$ which have 1's in the $2^{m_1}, \ldots, 2^{m_i-1}$ positions and 0 in the $2^{m_i}$ position. It can be shown that

$$S = S_1 \cup \ldots \cup S_k,$$

(19)
and furthermore, that the union on the right-hand side of (19) is disjoint.

To show (19), let \( x \in S \). Then \( x \) must differ from \( 2^{m_1} + \ldots + 2^{m_k} \) at some first point \( 2^{m_i} \) since \( x < 2^{m_1} + \ldots + 2^{m_k} \); hence \( x \in S_i \). Reverse containment is trivial since the sets \( S_1, \ldots, S_k \) are all subsets of \( S \). To show that the union on the right-hand side of (19) is disjoint, let \( i \) and \( j \) be distinct elements of \( \{ 1, \ldots, k \} \) and suppose without loss of generality that \( i > j \). Let \( x_i \) and \( x_j \) be arbitrary members of \( S_i \) and \( S_j \), respectively. Then \( x_i \) has a 1 at the \( 2^{m_i} \) position, and \( x_j \) has a 0 at the \( 2^{m_j} \) position; hence \( x_i \neq x_j \) and \( S_i \cap S_j = \emptyset \) for all \( i \neq j \).

By the above conditions, it follows that

\[
|S| = |S_1| + \ldots + |S_k|.
\]

Let \( i \in \{ 1, \ldots, k \} \) and consider \( |S_i| \). This is the number of integers of weight \( r \) which are less than \( 2^{m_1} + \ldots + 2^{m_k} \), have 1's in the \( 2^{m_1}, \ldots, 2^{m_{i-1}} \) positions, and a 0 in the \( 2^{m_i} \) position. There are \( m_i \) other positions \( 2^{m_1}, \ldots, 2^0 \) from which to choose \( r - (i - 1) = r - i + 1 \) positions to place 1's to form a binary word of weight \( r \), giving

\[
|S_i| = \binom{m_i}{r - i + 1};
\]

hence

\[
|S| = \binom{m_1}{r} + \binom{m_2}{r - 1} + \ldots + \binom{m_k}{r - k + 1}.
\]

Since this is equivalent to \( [m_1, \ldots, m_k]_r \) by definition, the proof of Lemma 2 is complete.

**Lemma 3.** Let \( S \) be the \( m \) first nonnegative integers of weight \( r \). Then the number of integers of weight \( s \) in \( r(S) \) is \( m^{(s/r)} \), and \( r(S) \) is the set of all nonnegative integers, which are less than \( 2^{m_1} + \ldots + 2^{m_k} \), if \( m = [m_1, \ldots, m_k]_r \) is the \( r \)-canonical representation of \( m \).

Lindström executes the proof of this lemma in [4]. Recall that \( r(S) \) is the set of binary words related to \( S \). For simplicial complexes, the boundary of a face, or binary word, of the complex is obtained by changing a 1 in one position to a 0.
Hence, a binary word of weight \( s < r \) is in \( r(S) \) if there exists a binary word \( j \in S \) such that \( i \subset j \) where \( i \) and \( j \) are viewed as sets. A binary word of weight \( s > r \) is in \( r(S) \) if all binary words \( j \) of weight \( r \) which satisfy \( j \subset i \) are contained in \( S \), where \( i \) and \( j \) are viewed as sets.

Once it has been shown that \( r(S) \) is the set of binary words that are less than \( M = 2^{m_1} + \ldots + 2^{m_k} \), application of Lemma 2 shows that the number of binary words of weight \( s \), which are less than \( 2^{m_1} + \ldots + 2^{m_k} \), is \([m_1, \ldots, m_k]_s\). Since \( m = [m_1, \ldots, m_k] \), then \([m_1, \ldots, m_k]_s = m^{(s/r)}\) by definition, and Lemma 3 follows. It remains to show

\[
r(S) = \{ i < 2^{m_1} + \ldots + 2^{m_k} : i \text{ is a binary word} \}.
\]  

(20)

Let \( M = 2^{m_1} + \ldots + 2^{m_k} \) For the forward inclusion of (20), let \( i \in r(S) \), and let \( s \) be the weight of \( i \). If \( s < r \), since there is a binary word \( j \in S \) such that \( i \subset j \), \( i < M \) follows.

If \( s > r \), assume to the contrary that \( i \geq M \). Then for some integers \( n_1, \ldots, n_r \),

\[
i = 2^{n_1} + \ldots + 2^{n_r} \geq 2^{m_1} + \ldots + 2^{m_k} = M.
\]

If \( j = 2^{n_1} + \ldots + 2^{n_r} \), then \( j \) is a binary word of weight \( r \) which satisfies \( j \subset i \); hence \( j \in S \). Then \( i \geq M \) and \( j < M \) imply \( n_1 = m_1, \ldots, n_r = m_r \), and \( k > r \). But by the \( r \)-canonical representation of \( m \), \( k \leq r \) must hold - a contradiction. Thus \( i < M \) and the forward inclusion of (20) holds.

To prove the reverse inclusion, let \( i < M \) be a binary word of weight \( s \). If \( s < r \) then for some index \( l < k \) these inequalities result:

\[
2^{m_1} + \ldots + 2^{m_l} \leq i < 2^{m_1} + \ldots + 2^{m_{l+1}}, \quad \text{or} \quad i < 2^{m_l}.
\]

In the first case \( m_{l+1} \geq r - l \geq 1 \) follows from the \( r \)-canonical representation of \( m \). Since \( (s-l) \)'s of \( i \) occur in the right-most \( m_{l+1} \) positions \( 2^{m_{l+1}-1}, \ldots, 2^0 \), there are
enough remaining 0’s in these positions to construct a \( j \) of weight \( r \) which satisfies \( i \subset j \) and

\[
2^{m_1} + \ldots + 2^{m_l} \leq j < 2^{m_1} + \ldots + 2^{m_{l+1}}.
\]

Thus \( j \in S \) and \( i \in r(S) \) follows by definition. In the second case, by definition of \( r \)-canonical form, \( m_1 \geq r \); there are at least \( r \) positions to the right of \( 2^{m_1} \); constructing \( j \) by starting with \( i \) and then filling in \( (r-s) \) other of these positions demonstrates a \( j \) which satisfies \( i \subset j \) and \( j < M \); hence, \( i \in r(S) \) by definition.

If \( s > r \), then all binary words \( j \) of weight \( r \) for which \( j \subset i \) also satisfy \( j < M \); thus these binary words of weight \( r \) are all in \( S \), and \( i \in r(S) \) by definition. This completes the proof of Lemma 3.
B Appendix: Sample Program for Computation

Below is the listing of a utility program (written in C) that computes various quantities relating to cubical and simplicial complexes. Its purpose is to compute upper semipowers, as in Kruskal's Theorem; lower semipowers, as in Lemma 5; optimal number of faces of cubical complexes, as in Theorem 2; and validation of $f$-vectors of cubical complexes, as in Theorem 3. This program was used to create Tables 1 and 2.

```

7404 Cedar Run Drive  
Warrenton, VA 22186  
robellis@math.vt.edu

Education  
California Institute of Technology, 1990-1992  
Virginia Polytechnic Institute and State University  
1993-1994: B.S., Mathematics  
1995-1996: M.S., Mathematics  
University of California at San Diego  
1996-: Ph.D. program, Mathematics

Work Experience  
Sum I, 1996; Spring 1996; Virginia Tech Graduate Teaching Assistant  
Fall 1995; Sum I, 1995; Spring 1995  
In reverse chronological order by term, responsibilities were: teaching freshman linear algebra, grading for freshman calculus, teaching two sections of freshman pre-calculus, grading for senior level numerical analysis, and working in the mathematics department tutoring lab.

8/93-12/94 Self-Employed Tutor  
While completing a B.S. in math, I worked as a tutor for various subjects in mathematics and computer science, ranging from freshman to junior level courses.

6/93-7/93, 10/15/92-1/7/93 DataFocus, Inc. Consultant  
I contributed to the development of an in-house relational database business system using PowerBuilder and Oracle on the Windows/PC platform.

6/91-9/91 Sparrow Consulting Consultant  
6/90-7/90 NSF/MS State Univ. Physics Dept. Programmer  
I developed improvements for an in-house data collection program (Kmax) using Macintosh Programmer’s Workshop, C, and Pascal on the Macintosh System 6.0 and 7.0 platforms, including an application specific program for analyzing radiation data taken from the Long Duration Exposure Facility (LDEF).

Publications  
A Kruskal-Katona Theorem for Cubical Complexes, Master’s Thesis (1996), for the completion of the degree of Master of Science (Mathematics) at Virginia Polytechnic Institute and State University.
