Incoherent bandpass spatial filtering with longitudinal periodicity

Ting-Chung Poon and Guy Indebetouw

We explore the possibility of realizing bandpass filtering with longitudinal periodicity in incoherent systems. The necessary condition for spatial filtering to be longitudinally periodic is derived. Results indicate that bandpass filtering with longitudinal periodicity can be achieved in a two-pupil system with Fresnel zone plates with a small opening ratio as the pupils.

1. Introduction

The phenomenon of wave field replication without imaging elements is commonly known as the self-imaging effect. This effect has been observed and studied extensively \(^ {1-5}\) and found applications in areas such as interferometry, \(^ \text{6,7}\) spatial filtering, \(^ \text{8,9}\) and acoustooptics. \(^ \text{10}\) We explore the possibility of achieving spatial filtering with longitudinal periodicity in incoherent systems. By filtering with longitudinal periodicity we mean that a certain spatial filtering operation in the transverse directions \((x,y)\) is repeated along the longitudinal direction \((z)\) at a periodic distance. Such systems may find applications in 3-D information processing, coding, structured illumination, and in 3-D space variant filtering. Specifically, the aspect of incoherent bandpass filtering is emphasized in this paper. Optical transfer functions (OTFs) with bandpass characteristics cannot be synthesized in conventional single pupil systems. One, therefore, needs to use the method of pupil function replication \(^ {11}\) or employ two-pupil systems. \(^ {12-16}\) In Sec. II we develop the mathematical formalism used to describe the response of a defocused two-pupil system. The condition under which the OTF is longitudinally periodic is derived in Sec. III. Section IV describes how a Fresnel zone plate (FZP) can act as a self-imaging pupil. In Sec. V, we consolidate the results of Sec. III and IV to investigate bandpass filtering with longitudinal periodicity in a two-pupil system. Calculated results are obtained and shown to be consistent with theoretical predictions. Finally, in Sec. VI, are some concluding remarks.

II. Defocused OTF of Two-Pupil Systems

It is well known that the defocused OTF of an incoherent imaging system can be expressed as the autocorrelation of a defocused pupil function \(^ {17}\):

\[
\text{OTF}(\rho, z) = P(\rho, z) * P(\rho, z) = \int P(\rho') P^*(\rho') \exp\left[j \pi \lambda z (\rho^2 - \rho'^2) \right] d^2 \rho'.
\]

(1)

Here \(P(\rho, z)\) is the defocused pupil function given by

\[
P(\rho, z) = p(\rho) \exp\left(j \pi \lambda x z \rho^2 \right),
\]

(2)

where \(p(\rho)\) is the in-focus pupil function, \(\lambda\) is the wavelength, and \(z\) is the defocused distance measured away from the focal plane of the second lens in Fig. 1.

For a given aperture function \(A(\tilde{\rho})\) located in the \(\tilde{\rho}\)-plane as shown in Fig. 1, the corresponding defocused pupil, expressed in terms of the spatial frequency \(\rho = r/\lambda f\), for a focal length \(f\) and in the paraxial approximation is given by

\[
P(\rho, z) = A(\lambda f \rho) \exp\left(j \pi \lambda x \rho^2 \right).
\]

(3)

For a two-pupil system \(^ {12,13}\) the defocused pupil is

\[
P(\rho, z) = U(\rho, z) + V(\rho, z),
\]

(4)

where \(U(\rho, z) = u(\rho) \exp\left(j \pi \lambda x \rho^2 \right)\) and \(V(\rho, z) = v(\rho) \exp\left(j \pi \lambda x \rho^2 \right)\). Thus the corresponding defocused OTF of the two-pupil system becomes, using Eq. (1),

\[
\text{OTF} = U*U + V*V + U*V + V*U.
\]

(6)

Note that the autocorrelation terms are always of low pass characteristics. To achieve spatial filterings with properties other than low pass, the cross-terms need to be extracted. The cross-correlation of the interactive terms can be separated from the autocorrelation (non-interactive) terms by the use of a spatial frequency offset \(^ {18-20}\) or a temporal frequency offset. \(^ {21}\)

pupil interaction processing technique, in which both spatial carrier and temporal carrier offset are brought about by acoustooptics, has also been described.\(^2\) In the acoustooptic two-pupil interactive systems, the defocused OTF is the cross-correlation of the two defocused pupils.\(^2\) Using Eqs. (1) and (4), we have
\[
\text{OTF}(\vec{\rho}, z) = U \star V = \int u(\vec{\rho}) u^*(\vec{\rho}') \exp[j\pi \lambda z(\vec{\rho} - \vec{\rho}')^2] d^2\rho'.
\]

A real time system based on the acoustooptic approach has been described for realizing simultaneously a low pass filter and a first- and second-order differentiation.\(^2\) A similar system has been used recently for textural edge extraction.\(^2\)

### III. Condition for Longitudinally Periodic OTF

An OTF(\(\vec{\rho}, z\)), which is periodic in \(z\) with a period \(z_0\), can be expressed in terms of a Fourier series expansion:
\[
\text{OTF}(\vec{\rho}, z) = \sum_n a_n(\vec{\rho}) \exp(j2\pi nz/z_0).
\]

By equating Eqs. (7) and (6), we can establish the requirement for \(u(\vec{\rho})\) and \(v(\vec{\rho})\) so that the two pupils produce a spatial filtering function that repeats longitudinally at regular intervals \(z_0\):
\[
\int u(\vec{\rho}) v^*(\vec{\rho}') \exp[j\pi \lambda z(\vec{\rho} - \vec{\rho}')] d^2\rho' = \sum_n a_n(\vec{\rho}) \exp(j2\pi nz/z_0).
\]

To have the same functional dependence on \(z\) on both sides of Eq. (8), \(\vec{\rho}' - \vec{\rho}\) and \(\vec{\rho}'\) must take on discrete values. Thus \(u(\vec{\rho})\) and \(v(\vec{\rho})\) are nonzero only on discrete rings, and the two pupils must thus take the following form:
\[
u(\vec{\rho}) = \sum_m b_m(\vec{\rho}) \delta(\vec{\rho} - \vec{\rho}_m),\]
\[
u(\vec{\rho}) = \sum_n v_n(\vec{\rho}) \delta(\vec{\rho} - \vec{\rho}_n).
\]

Substituting Eq. (9) into Eq. (8), the OTF can then be written as
\[
\text{OTF}(\vec{\rho}, z) = \sum_n \sum_m \mu_n(\vec{\rho}) v_m(\vec{\rho}) \delta(\vec{\rho} - \vec{\rho}_n) \delta(\vec{\rho} - \vec{\rho}_m) \times \exp[j\pi \lambda z(\vec{\rho}^2 - \vec{\rho}_n^2 - \vec{\rho}_m^2)] d^2\rho' = \sum_n \sum_m \mu_n v_m C(\rho_n, \rho_m, \vec{\rho}) \times \exp[j\pi \lambda z(\vec{\rho}^2 - \vec{\rho}_n^2 - \vec{\rho}_m^2)],
\]

where \(C(\rho_n, \rho_m, \vec{\rho})\) is the intersection of the two rings \(\delta(\vec{\rho} - \vec{\rho}_n)\) and \(\delta(\vec{\rho} - \vec{\rho}_m)\). The situation is illustrated in Fig. 2.

Now, comparing the exponentials of Eqs. (10) and (7), it is evident that \(\rho_n^2 - \rho_m^2\) must be an integer. Thus we have
\[
\rho_n^2 = n\rho_1^2,
\]
\[
\rho_m^2 = m\rho_1^2.
\]

---

3346 APPLIED OPTICS / Vol. 29, No. 23 / 10 August 1990
The OTF characteristics are determined by the coefficients \( y_n \) and \( m \) which, in general, may be functions of an azimuthal angle \( \theta \) as well as by the intersection \( C_{n,m} \) of the rings. The periodic distance \( z_0 \) is wavelength dependent and a function of the radius \( \rho_1 \) of the first rings.

**IV. Fresnel Zone Plate as a Self-Imaging Pupil**

The ring pupils found in Eq. (12) are Fresnel zone plate (FZP) apertures with a vanishingly small opening ratio. A practical realization of such apertures will obviously have a finite opening ratio. Such an unbounded FZP aperture has a transmission function given by

\[
\mathcal{A}(\rho) = \sum_{n} A_n \exp\left(j2\pi n \frac{\rho^2}{R_1^2}\right),
\]

where \( R_1 \) is the radius of the first zone, and

\[
A_n = \frac{\sin n\pi}{n\pi}
\]

for a FZP having an opening ratio \( \alpha \). Note that here the coefficients \( A_n \) are constants, while in the general expression (7) for the \( z \)-periodic OTF, the coefficients \( a_i \) can vary with an azimuthal angle \( \theta \). If this FZP, placed in the \( r \)-plane in Fig. 1, is illuminated by a point source located in the front focal plane of the first lens, multiple foci are observed along the longitudinal \( z \)-direction. To find the distance between the foci, we first express Eq. (15) as a defocused pupil. On substituting Eq. (15) into Eq. (3), we obtain

\[
P(\rho, z) = \sum_{n} A_n \exp\left(j2\pi n \frac{\rho^2}{R_1^2}\right) \exp(j\pi \rho \phi).
\]

The amplitude of the point spread function (PSF) along the \( z \)-axis can then be found by evaluating the Fourier transform of Eq. (16) at \( x = y = 0 \), giving

\[
h(z) = \left[ \sum_{n} A_n \exp\left(j2\pi n \frac{\rho^2}{R_1^2} \right) \exp(j\pi \rho \phi) \right] 2 \pi \rho d\rho
\]

\[
= \sum_{n} A_n \delta \left(z + n \frac{2\lambda^2}{R_1^2}\right).
\]

where \( A_n \) has absorbed all constants resulting from evaluation of the integral. With a FZP of finite size, the \( \delta \)-functions are convolved with a smoothing function, the width of which is inversely proportional to the radius of the outermost zone. From Eq. (17), we see that the point source is imaged at locations given by

\[
z_n = n \frac{2\lambda^2}{R_1^2}.
\]

These are the positions at which the self-images appear. The distance \( z_0 \) between the self-images is \( 2\lambda^2/R_1^2 \). Note that the intensity at \( z_n \) is proportional to \((A_n)^2\). To obtain equal intensity at these locations, the \( A_n \) terms should be independent of \( n \). This occurs if the opening ratio of the zones approaches zero because \( A_n \rightarrow \alpha \) as \( \alpha \rightarrow 0 \). Therefore, a thin FZP can be used as an approximate self-imaging pupil.

**V. Bandpass Filtering with Longitudinal Periodicity**

To achieve bandpass filtering, the two pupils must be distinct so that their cross correlation produces the desired spatial frequency response. In particular, for a bandpass filter, the dc should not be transmitted. This means that the overlap area of the two apertures should vanish. To ensure filtering with longitudinal periodicity, the pupils must also be of the self-imaging type. Hence bandpass filtering with longitudinal periodicity can be accomplished by employing, for example, the following apodized FZP pupils in a two-pupil interaction system:

\[
u(s) = \exp(-\rho^2 \phi^2/2)
\]

\[
u(\rho) = \exp\left(-\rho^2 \frac{\lambda^2}{R_1^2}\right)
\]

where

\[
A_n = \sin n\pi \quad \text{and} \quad A_m = \sin m\pi
\]

The terms \( u(\rho) \) and \( v(\rho) \) are two FZPs with Gaussian apodizations. The apodization is introduced to limit the number \( N \) of zones in the pupil while still leading to an analytical solution for the OTF. In addition, this apodization may be thought of as representing the effect of a Gaussian light beam illumination. The opening ratios \( \alpha \) and \( \beta \) in Eqs. (19) are <0.5 to ensure that the two pupils have no common area of clear aperture. Figure 3 shows the unapodized FZPs. To obviate the specification of specific dimensions, we introduce the following normalized coordinates:

\[
\hat{\rho} = \frac{\rho \lambda f}{R_1}, \quad \hat{\xi} = \frac{z}{z_0},
\]

where \( z_0 = 2\lambda f^2/R_1^2 \) is the distance between the foci. Substituting Eq. (19) into Eq. (6) and using the normalization parameters in Eqs. (20), we find

\[
A_n = \sin n\pi \quad \text{and} \quad A_m = \sin m\pi
\]

The terms \( u(\rho) \) and \( v(\rho) \) are two FZPs with Gaussian apodizations. The apodization is introduced to limit the number \( N \) of zones in the pupil while still leading to an analytical solution for the OTF. In addition, this apodization may be thought of as representing the effect of a Gaussian light beam illumination. The opening ratios \( \alpha \) and \( \beta \) in Eqs. (19) are <0.5 to ensure that the two pupils have no common area of clear aperture. Figure 3 shows the unapodized FZPs. To obviate the specification of specific dimensions, we introduce the following normalized coordinates:

\[
\hat{\rho} = \frac{\rho \lambda f}{R_1}, \quad \hat{\xi} = \frac{z}{z_0},
\]

where \( z_0 = 2\lambda f^2/R_1^2 \) is the distance between the foci. Substituting Eq. (19) into Eq. (6) and using the normalization parameters in Eqs. (20), we find

\[
\mathcal{A}(\rho) = \left[ \sum_{n} A_n \exp\left(j2\pi n \frac{\lambda^2 \rho^2}{R_1^2}\right) \right]
\]

\[
\mathcal{A}(\rho) = \left[ \sum_{n} (-1)^m A_n \exp\left(j2\pi m \frac{\lambda^2 \rho^2}{R_1^2}\right) \right]
\]

Fig. 3. Fresnel zone plate apertures plotted against the normalized coordinate \( \hat{\rho}^2 = (\rho \lambda f)/R_1^2 \) used to approximate a longitudinally periodic bandpass filter.
Fig. 4. \(|\text{OTF}| \) vs \(\beta\) as a function of \(\xi\), the normalized defocused distance. The opening ratios of the FZPs are \(\alpha = \beta = 0.5\) and \(N = 9\): (a) \(\xi = 0\), (b) \(\xi = 0.5\), (c) \(\xi = 1\), (d) \(\xi = 1.5\)
(Fig. 5 continued)
OTF(\(\xi, \xi\)) = \sum_n \sum_m A_n A_m (\frac{1}{2\pi})^{\frac{n}{N}} \\
\times \exp \left( -\frac{\hbar^2 N}{4} (n-m)^2 + \frac{\pi(n + m + 2\xi)^2}{12} \right), \quad (21)

where

\[
\frac{1}{N} = \frac{2}{N} = j2\pi(n - m).
\]

In what follows, we present some numerical results showing the evolution of the OTF given in Eq. (21) with the normalized defocus distance \(\xi\). Two cases are shown. In the first case, we take \(\alpha = \beta = 0.5\), which corresponds to having complementary pupils. \(N\) is taken to be 9. Figure 4 shows the OTFs at various distances \(\xi\). In the second case, \(\alpha = \beta = 0.1\), which is a good approximation to the thin ring pupils given by Eq. (12). Figure 5 shows the results. We indeed observe that the OTF is of bandpass characteristics and is periodic along \(z\) with a periodic distance \(z_0\).

### VI. Conclusions and Remarks

We have explored the possibility of realizing an incoherent spatial filtering which is repeated periodically along \(z\). The condition for \(z\)-periodicity is that the domain of the two interacting pupils be limited to discrete Montgomery rings of radii proportional to the \(\sqrt{n} \) (\(n = \text{integer}\)). We have shown that by employing Fresnel zone plates as the pupils in a two-pupil system, bandpass filtering with longitudinal periodicity can be achieved. Such periodic behavior of a spatial filtering operation may have potential applications in 3-D image processing or coding. As a final note we want to point out that in Eq. (9) \(\mu_n\) and \(\nu_m\) can in general be a function of the azimuthal angle \(\theta\). Rings with modulation along \(\theta\) may give rise to other interesting or more general (nonrotationally symmetric) spatial filtering operations.
