ABSTRACT: Besnoitia darlingi and Besnoitia neotomofelis are cyst-forming tissue apicomplexan parasites that use domestic cats (Felis domesticus) as definitive hosts and opossums (Didelphis virginiana) and Southern Plains woodrats (Neotoma micropus) as intermediate hosts, respectively. Nothing is known about the prevalence of B. darlingi or B. neotomofelis in cats from the United States. Besnoitia darlingi infections have been reported from naturally infected cats in the United States, and B. neotomofelis infections have been reported from Southern Plains woodrats in Texas, but naturally infected cats have not been identified. The present study examined the IgG antibody response of cats to experimental infection (B. darlingi n = 1 cat; B. neotomofelis n = 3 cats). Samples from these cats were used to develop an indirect immunofluorescent antibody test (IFAT), which was then used to examine seroprevalence of IgG antibodies to tachyzoites of B. darlingi and B. neotomofelis in a population of domestic cats from Virginia (N = 232 cats) and Pennsylvania (N = 209). The serum from cats inoculated with B. darlingi or B. neotomofelis cross-reacted with each other’s tachyzoites. The titers to heterologous tachyzoites were 1 to 3 dilutions lower than to homologous tachyzoites. Sera from B. darlingi- or B. neotomofelis-infected cats did not react with tachyzoites of Toxoplasma gondii or Neospora caninum or merozoites of Sarcocystis neurona using the IFAT. Antibodies to B. darlingi were found in 14% and 2% of cats from Virginia and Pennsylvania, respectively. Antibodies to B. neotomofelis were found in 5% and 4% of cats from Virginia and Pennsylvania, respectively. Nine cats from Virginia and 1 cat from Pennsylvania were positive for both.

Besnoitia is a group of cyst-forming tissue apicomplexan parasites, some of which are of veterinary significance. Several Besnoitia species cause fatal infections and economic losses in domestic animals and wildlife in various countries (Dubey, 2009; Mehlhorn et al., 2009). Besnoitia darlingi uses cats and opossums in its life cycle. The Virginia opossum (Didelphis virginiana) is the intermediate host, and domestic cats (Felis domesticus) are definitive hosts. Cats become infected by ingesting tissue cysts from opossums and produce oocysts that are shed in the feces (Smith and Frenkel, 1977, 1984; Dubey et al., 2002). Ten species of Besnoitia have been described, and domestic cats are the definitive hosts for the 4 species with known life cycles (reviewed by Dubey and Yabsley, 2010; Kiehl et al., 2010). The life cycles of the remaining 6 Besnoitia species are presently unknown.

Little is known about the epidemiology of B. darlingi in cats from the United States. Besnoitia darlingi tissue cysts or antibodies have been described in opossums from Illinois, Indiana, Kentucky, Louisiana, Michigan, Missouri, and Texas (reviewed by Houk et al., 2010). Natural B. darlingi infections have been diagnosed in United States opossums (Houk et al., 2010); however, naturally infected cats have not yet been identified (Dubey et al., 2002), and there is no information regarding the prevalence of B. darlingi in cats in the United States. This is due to the difficulty in identifying Besnoitia spp. oocysts and in differentiating them from oocysts of Toxoplasma gondii in cat feces. Moreover, Besnoitia sp. antigen is unavailable commercially and must be grown in cell culture systems.

Besnoitia neotomofelis Dubey and Yabsley, 2010 was described from naturally infected Southern Plains woodrats (Neotoma micropus). Laboratory mice (Mus musculus) and rats (Rattus norvegicus) have been shown to be intermediate hosts, and cats have been identified as the definitive host (Dubey and Yabsley, 2010). Phylogenetic analysis using the 18S rRNA gene and the ITS-1 region indicated that B. neotomofelis is distinct from B. darlingi, Besnoitia wallacei, and Besnoitia oryctofelisi, all of which utilize cats as a definitive host (Dubey and Yabsley, 2010).

The present study was conducted to investigate the serological response of cats to inoculation with tachyzoites of B. darlingi and B. neotomofelis and to determine the seroprevalence of antibodies to these 2 Besnoitia species in cats from Virginia and Pennsylvania. In addition, we also evaluated the indirect immunofluorescent antibody test (IFAT) using sera from experimentally infected cats for cross-reactivity to stages of T. gondii, Neospora caninum, and Sarcocystis neurona.

MATERIALS AND METHODS

Parasite cultivation

Tachyzoites of B. darlingi (strain of Dubey et al., 2002) and B. neotomofelis (strain of Dubey and Yabsley, 2010) were grown separately in human foreskin fibroblasts (HS68, ATCC CRL1635, Manassas, Virginia) that had grown to confluence in 75-mm² tissue culture flasks. Growth media consisted of 10% Fetal Bovine Serum (FBS) (v/v) in RPMI 1640 medium, supplemented with 100 U penicillin/ml and 100 mg streptomycin/ml. After monolayers had reached confluence, the growth medium was removed and replaced with a maintenance medium that was identical to the former, except the volume of FBS was 2% (v/v). Flasks were incubated at 37°C in a humidified incubator containing 5% CO₂ and 95% air. Additionally, tachyzoites of the RH strain (Sabin, 1941) of T. gondii and the NC-1 strain (Dubey et al., 1988) of N. caninum were grown in HS68
cells, and merozoites of the SN-37R isolate (Sofaly et al., 2002) of *S. neurona* were grown and maintained in African green monkey (*Cercopithecus aethiops*) kidney cells (CV-1, ATCC CCL-70, ATCC) using techniques identical to those described for H68 cells.

**Experimental inoculation of cats**

Four 3- to 4-mo-old cats from the parasite-free colony (Dubey, 1995) housed at the United States Department of Agriculture, Animal Parasitic Diseases Laboratory, Beltsville, Maryland, were used to examine the IgG antibody response to *B. darlingi* and *B. neotomofelis*. Cat 77 was inoculated subcutaneously with 1 × 10⁶ tachyzoites of *B. darlingi*, and serum samples were collected on days 0, 7, and 36 postinoculation (PI). Two cats (90, 91) were fed infected mouse tissues containing *B. neotomofelis* tissue cysts; the mice had been fed *B. neotomofelis* oocysts 5 mo earlier. Both cats remained asymptomatic and shed *B. neotomofelis* oocysts 12–25 (cat 90) and 13–20 (cat 91) day PI. Sera samples were collected from these cats on days 0, 26, and 40 PI. An additional sample from cat 90 was collected on day 10 PI. Cat 78 was inoculated subcutaneously with 1 × 10⁵ cell culture–derived *B. neotomofelis* tachyzoites, and serum samples were collected on days 0, 7, and 36 PI. Sera samples were shipped by overnight carrier to the Center for Molecular Medicine and Infectious Diseases (CMMID), Virginia–Maryland Regional College of Veterinary Medicine, Blacksburg, Virginia, and stored at 4 C until examined. Sera samples were used at an initial dilution of 1:50 and end-point titrated (Table I). Sera samples from all 4 cats were examined for titers against *B. darlingi* and *B. neotomofelis* on each sample collection day. Sera samples collected from last evaluation period (days 36 or 40 PI) were used to examine specificity of the test using *T. gondii*, *N. caninum*, and *S. neurona* stages as antigens.

**Feline samples and immunofluorescent antibody test**

Feline serum or plasma samples were obtained from 441 cats for the present study (Hsu et al., 2010). Serum or plasma samples were collected from 232 cats from Virginia as part of an ongoing study of kidney disease conducted at the Department of Small Animal Clinical Science, at the Virginia–Maryland Regional College of Veterinary Medicine, Blacksburg, Virginia. An additional 209 serum samples were acquired from an animal shelter in Philadelphia, Pennsylvania. These samples were initially used in a study of the seroprevalence of *T. gondii* (Dubey et al., 2008). Serum and plasma samples were stored at −20 C until used.

For collection of parasites for the IFAT, infected H68 or CV-1 cells were removed with a cell scraper, the media mixture was filtered through 3-μm polycarbonate filters (GE Water and Process Technologies, Minnetonka, Minnesota), and parasites were pelleted by centrifugation. After 3 washes in phosphate-buffered saline (PBS), the cell suspension containing approximately 0.5–1 × 10⁵ tachyzoites/merozoites in 25 μl of PBS was dispensed into each well of a 12-well Teflon-coated IFAT slide (Fisher Scientific, Pittsburgh, Pennsylvania). Antigen-containing slides were then left to dry at room temperature for 4 to 12 hr and stored at −20 C until used.

Cat serum or plasma samples were diluted at 1:100 in PBS, and 25 μl were pipetted into each well of the antigen-containing slides. The slides were incubated for 30 min at room temperature in a humidified chamber. Subsequent to 2 consecutive washes in PBS, fluorescence-labeled goat anti-rabbit IgG (Kirkegaard and Perry Labs Inc., Gaithersburg, Maryland) was diluted 1:5 in PBS, and 25 μl aliquots were added to each well of the slides. The slides were incubated for 30 min at room temperature in a humidified chamber. Following 3 consecutive washes in PBS, slides were mounted in Fluoromount-G (Southern Biotechnology Associates Inc., Birmingham, Alabama), and examined using an Olympus BX60 epifluorescent microscope equipped with differential contrast optics (Olympus America Inc., Center Valley, Pennsylvania). Samples that exhibited fluorescence of the entire parasitic surface were considered to be positive.

**RESULTS**

None of the experimentally infected cats were seropositive to *B. darlingi* or *B. neotomofelis* prior to inoculation (Table I). All cats seroconverted to the *Besnoitia* species inoculated and demonstrated cross-reactive reactions with the *Besnoitia* species not inoculated. None of the serum samples from cats experimentally inoculated with *B. darlingi* or *B. neotomofelis* collected on any examination day PI reacted with stages of *T. gondii*, *N. caninum*, or *S. neurona* in the IFAT. No reactivity to *B. darlingi* was observed in cats that had previously tested positive for antibodies to *T. gondii* or *S. neurona* (Dubey et al., 2008; Hsu et al., 2010).

Antibodies to *B. darlingi* and *B. neotomofelis* were found in 14% and 5% cats, respectively, from Virginia. Nine of these cats were positive for both *B. darlingi* and *B. neotomofelis*. Antibodies to *B. darlingi* and *B. neotomofelis* were found in 3 and 5 cats, respectively, from Pennsylvania. One of these cats was positive for both *B. darlingi* and *B. neotomofelis*.

**DISCUSSION**

*Besnoitia* spp. parasitize domestic and wild animals. In some parts of the world, these parasites cause serious economic losses in cattle. Ten species of *Besnoitia* have presently been named (Dubey and Yabsley, 2010), but the life cycle is not known for any species. Cats have been identified as the definitive host for *B. wallacei*, *B. darlingi*, *B. oryctofelisi*, and the recently recognized species *B. neotomofelis* (Dubey and Yabsley, 2010).

Smith and Frenkel (1984) examined the serological response to *B. darlingi* inoculation of opossums and cats using tachyzoites of *Besnoitia jellisoni* as an antigen in the Sabin-Feldmen dye test (SFDT). Sera samples from 5 opossums inoculated with tissue cysts oocysts, tachyzoites, or a mixture of all 3 stages seroconverted to *B. jellisoni* in the SFDT. They (Smith and Frenkel, 1984) reported that 2 cats given *B. darlingi* oocysts did not seroconvert in the SFDT or excrete oocysts. Five of 14 cats given *B. darlingi* tissue cysts demonstrated seroconversion to *B. jellisoni* in the SFDT, and all 14 cats excreted oocysts (Smith and Frenkel, 1984). This suggests that intestinal infection with stages of *B. darlingi* does not induce a strong serological response. Interestingly, 2 of 4 cats challenged with *B. darlingi* after excreting oocysts were susceptible to repeat oocyst excretion (Smith and Frenkel, 1984). The cat in the present study inoculated with

* Tachyzoites.
† Tissue cysts.
tachyzoites seroconverted to homologous antigen in the IFAT. The results of our study are difficult to compare to those of Smith and Frenkel (1984) because different serological tests and different strains of *B. darlingi* and modes/stages were used to administer parasites. We demonstrated cross-reactivity of cat *B. darlingi* anti-sera with *B. neotomofelis* antigen and cross-reactivity of cat *B. neotomofelis* anti-sera with *B. darlingi* in the present study, and this is consistent with the finding of cross-reactivity of cat *B. darlingi* anti-sera with *B. jellisoni* antigen reported by Smith and Frenkel (1984). We also demonstrate that antibodies in cat sera to *B. darlingi* or *B. neotomofelis* were not cross-reactive to *T. gondii*, *N. caninum*, or *S. neurona* in the IFAT. Lunde and Jacobs (1965) demonstrated cross-reactivity of *B. jellisoni* and *T. gondii* in rabbit sera using the hemagglutination test, but not the dye test.

This is the first report to use the IFAT to examine the prevalence of exposure of domestic cats to *B. darlingi*. In the United States, *B. darlingi* tissue cysts have been reported from 1 of 1 opossums from Illinois (Flatt et al., 1971), 6 of 6 from Indiana (Jack et al., 1989), 1 of 5 (20%) from Kentucky (Conti-Diaz et al., 1970), 1 of 1 from Louisiana (Shaw et al., 2009), 15 of 137 (11%) from Michigan (Elsheikha et al., 2003), 2 of 2 from Mississippi (Dubey et al., 2002), 7 of 12 (58%) from Missouri (Flatt et al., 1971; Smith and Frenkel, 1977), and 1 of 1 Texas (Stabler and Welch, 1961). Antibodies to *B. darlingi* have been described in 14 of 30 (47%) opossums from southern Louisiana using the IFAT (Houk et al., 2010). It is likely that *B. darlingi* is present throughout the range of opossums in North America.

Dubey and Yabsley (2010) reported that acid-pepsin-digested tissues from 1 of 38 woodrats from Texas were positive for *B. neotomofelis*. Tissue cysts of *B. neotomofelis* collected from experimentally infected rodents were infectious for 7 of 13 cats, which excreted few oocysts in their feces (Dubey and Yabsley, 2010). Extraintestinal stages of *B. neotomofelis* have been demonstrated in experimentally infected cats. No other studies have been conducted on the prevalence of *B. neotomofelis* in woodrats or other potential intermediate hosts.
