IV. INTRODUCTION

In modern space age travels, animals and mechanical and electrical apparatus will traverse long distances through an endless hostile environment of space. One of the more important aspects of the environment, which must be provided for the space traveler, is temperature control.

Basically, temperature controls have been developed along two lines, the passive and/or the active thermal control. Of course, the methods of passive thermal design may be incorporated into an active thermal design scheme. It is quite evident that passive temperature control is achieved at the time of construction of the spacecraft, as by the application of proper optical coatings, selection of spacecraft geometry and judicious selection of construction materials. On the other hand, active thermal control employs heat generating devices, refrigeration devices, and other similar systems. The role of passive thermal control is to provide, as nearly as possible, a suitable temperature environment, while the active method should be used only when necessary.

At present the near-earth spacecraft is a reality and its environmental situations include all those encountered by most spacecraft. In support of this premise the present thesis will consider only passive thermal design for near-earth satellites.

The two celestial bodies which dominate the heat transferred to a near-earth spacecraft are the earth and sun. The dominant mode of heat transfer to a spacecraft is by thermal radiation. The spacecraft
receives heat directly from the sun and/or earth; and is heated by the sun's rays which are reflected by the earth onto the vehicle.

There are many papers available in the literature written on the thermal design of spacecraft. Unfortunately, even though the subject is straightforward, the problems encountered in thermal design do not lend themselves well to closed form solutions. Consequently, solutions found in the literature are usually numerical and specialized, or they are analytical and solved under assumptions too rigid to be of general interest or to permit an insight into the problem itself.

The following analysis is intended to obtain analytical solutions of thermal control problems which are general in nature whenever this is possible. When the problems encountered do not permit general solutions to be obtained their methods of solution are presented in sufficient detail to provide the reader with enough "tools" to solve related types of problems. A parametric study of orbital heating which requires only a minimum knowledge of orbital variables is given. This clearly shows the nature and sources of orbital heating.
V. Definitions

$A$  
surface area, in.$^2$

$A_{i,j}$  
area of body (i) projected to body (j), in.$^2$

$A_i$  
area of general body projected to body (i), in.$^2$

$c_i$  
coefficient in a Fourier expansion

$a_{i,j}$  
absorption of radiation from body i by body j

$e_i$  
absorption of radiation from body i by a general body

$B_e$  
angle between ($\bar{a}_n$) and $-e_{2n}$, deg

$b_i$  
coefficient from expansion of $G_3$

$c$  
specific heat, Btu/lb $^\circ$R

$c_i$  
coefficient in a Fourier expansion

$c_{rn}$  
complex constant, $c_{rn} + ic_{rn}$ where $i = \sqrt{-1}$

$G_i$  
coefficient from expansion of $G_3$

$d_{rn}$  
complex constant

$\bar{e}_u$  
unit vector aligned with spacecraft momentum vector

$\bar{e}_{x_i}, \bar{e}_{y_i}, \bar{e}_{z_i}$  
unit vectors which form a right-hand orthogonal cartesian coordinate frame associated with the ith coordinate system

$\bar{e}$  
unit vector at the center of the spacecraft pointing toward the center of the earth

$\hat{c}_{rn}, \hat{e}_{rn}$  
coefficient in the expansion of $q(t)$

$E$  
angle measured from orbital ascending node to spacecraft, deg

$f_i$  
a function of orbit angle in the expansion of heat flux falling onto a spacecraft
\( f_{rn,E_{rn}} \) a function of the \( x \) coordinate in the temperature solution of a body with nonlinear radiation on its front face

\( F_{ik} \) integral value in the calculation of albedo heating on a spacecraft

\( G_{i} \) function appearing in the calculation of earth thermal and albedo heating

\( G_{1} \) function appearing in the solution of time-dependent temperature distributions

\( \ar{G}_{1} \) function appearing in the solution of time-dependent temperature distributions

\( h_{i} \) function appearing in the solution of time-dependent temperature distributions

\( h_{i,j} \) conductive heat-transfer coefficient for heat flow from body \( i \) to body \( j \), Btu/\(^{\circ}\)R

\( H \) heavieside step function

\( i \) angle between ecliptic plane and equatorial plane, deg

\( i \) square root of \((-1)\)

\( i,n,k,r \) summation indices

\( I \) angle between the equatorial plane and orbit plane, deg

\( J_{1} \) intensity of radiant heat leaving body \( i \), Btu/in.\(^2\) \cdot min

\( K \) thermal conductivity, Btu/min in. \(^{\circ}\)R

\( L \) orbit period, min

\( L_{1} \) time in sunlight per orbit period, min
mass, lb
\( M_1 \) coefficient in the expansion of solar heat on a spacecraft with cylindrical walls
\( M_n, N_n \) function of \( x \) in the temperature solution of a body with nonlinear radiation on its front face
\( \hat{n} \) unit vector normal to a surface
\( p \) power per unit volume generated in a body, Btu/min • in.\(^3\)
\( P \) total power generated in a body, Btu/min
\( q \) intensity of heat falling on a body, Btu/in.\(^2\) • min
\( \hat{q}_n \) normal component of heat intensity, Btu/in.\(^2\) • min
\( \hat{q}_r \) tangential component of heat flow in a body, Btu/min • in.\(^2\)
\( C \) rotation matrix
\( Q_{ij} \) components of a rotation matrix
\( \hat{Q} \) heat content of a body, Btu
\( \hat{Q}_R \) mean radiation intensity from a body, Btu/min • in.\(^2\)
\( \hat{Q}_k \) mean conduction intensity in a body, Btu/in.\(^2\) • min
\( R_T \) distance of spacecraft from earth's center, miles
\( R_1 \) distance between radiating bodies, miles
\( r_e \) earth albedo (0.4)
\( r \) radial coordinate in cylindrical polar coordinates, in.
\( R_e \) radius of earth, miles
\( R \) distance between radiating bodies, miles
\( R_{ji} \) radiative heat transfer from body \( j \) to body \( i \), Btu/\( \alpha_R^4 \)
s  solar radiation constant, Btu/in.\(^2\) \cdot \text{min}
T  temperature, °R
\(t\) time, \text{min}
\(T_v\) volume averaged temperature, °R
\(T_r\) the \(r\)th temperature perturbation, °R
\(t_1\) dummy time variable, \text{min}
v variation of surface temperature from its mean value, °R
\(X,Y,Z\) inertial coordinate frame where the \(Z\) axis coincides with the north pole and the \(Y\) axis is perpendicularly to the earth-sun line at the time of the summer solstice
\(X',Y',Z'\) rectangular coordinate frame with the \(Z'\) axis normal to the orbit plane and the \(X'\) axis coinciding with the satellite-earth line
\(X'',Y'',Z''\) rectangular cartesian coordinate frame with the \(X''\) axis coincident to the earth-sun line and the \(Z''\) axis perpendicular to the ecliptic plane
\(X_b,Y_b,Z_b\) rectangular cartesian coordinate frame with the \(Z_b\) axis coinciding with the spacecraft axis of rotational symmetry
\(X_0,Y_0,Z_0\) rectangular cartesian coordinate frame with the \(Z_0\) axis coincident to the satellite-earth line and the \(X_0\) axis lying in the plane formed by the \(Z_0\) axis and the satellite's spin vector \(\vec{\Omega}\)
\(a^2\) thermal diffusivity, in.\(^2\)/\text{min}
\(\beta\) angle specifying the position of a radiating element on the earth's surface relative to the satellite subpoint, deg
\( \beta_s \) angle specifying the position of a reflecting element on the earth's surface relative to the sun's subpoint, deg

\( \gamma \) azimuth angle in spherical coordinates, deg

\( \delta \) orbit angle, deg

\( \phi \) cone half angle, deg

\( \dot{} \) time derivative of orbit angle, radian/min

\( \Delta \) factor measuring perturbation strength

\( \nabla \) del operator from vector calculus, in.\(^{-1}\)

\( \nabla^2 \) Laplacian operator from vector calculus, in.\(^{-2}\)

\( \epsilon \) sun's latitude relative to orbit plane coordinate system, deg

\( \zeta \) sun's longitude relative to orbit plane coordinate system with the perigee taken as 0°, deg

\( \zeta' \) angle measuring viewer's misalignment with a body's axis of rotational symmetry, deg

\( \psi \) angle between spacecraft's spin axis and satellite-earth line, deg

\( \psi' \) angle between spacecraft's spin axis and the satellite-sun line, deg

\( \theta_1 \) dummy variable, deg

\( \theta \) polar angle in spacecraft's spherical coordinate system, deg

\( \theta_0 \) limit of integration of polar angle in spacecraft's spherical coordinate system, deg

\( \lambda_0 \) initial angle between orbit perigee and ascending node, deg
\( \dot{\lambda} \) time derivative of \( \lambda \), deg/min

\( \lambda \) angle between orbital ascending node and perigee, deg

\((\lambda_T, \lambda_{TH}, \hat{\lambda}_{TH})\) heat rate ratios

\( V \) volume, in.\(^3\)

\( \hat{\zeta} \) azimuth angle in cylindrical polar coordinates aligned with the \((X_b,Y_b,Z_b)\) coordinate frame, deg

\( \mu \) projected area of body with unit surface area in short-term spin mode, dimensionless

\( \hat{\mu} \) projected area of body with unit surface area in long-term spin mode, dimensionless

\( \langle \hat{\mu} \rangle \) expectation value of \( \mu \) in random motion, dimensionless

\( \vec{v} \) unit vector from spacecraft's center pointing to viewer

\( \hat{v} \) latitude of spacecraft's spin axis (\( \hat{\zeta} \)) relative to orbit plane coordinate system, deg

\( \rho \) density, lb/in.\(^3\)

\( \hat{\psi} \) spin angle of spacecraft's axis of rotational symmetry about spin vector (\( \vec{v} \)), deg

\( f_n \) dimensionless temperature perturbation

\( \sigma \) Stephan-Boltzmann constant, \( 2 \times 10^{-13} \) Btu/in.\(^2\) · min · \( \circ R \)^4

\( t \) shell thickness, in.

\( f_n \) \( n \)th term of the modified forcing function, Btu/in.\(^2\) · min

\( r_n \) volumetric radiation intensity, Btu/in.\(^3\) · min

\( \phi_{i}, \hat{j} \) total heat flux on body \( j \) from body \( i \), Btu/min

\( \phi_{i,j} \) total heat intensity on body \( j \) from body \( i \), Btu/in.\(^2\) · min

\( \phi_{0} \) initial angle between \( X \) axis and ascending node of orbit, deg
\( \varphi_{AN} \)  
angle between X axis and ascending node of orbit, deg

\( \dot{\varphi} \)  
time derivative of \( \varphi_{AN} \), rad/min

\( \lambda \)  
longitude of spacecraft's spin vector (\( \hat{n} \)) in orbit plane 
coordinate system with perigee taken as \( \pm x/2 \), deg

\( \gamma \)  
largest difference between \( \langle \hat{n} \rangle \) and \( \hat{n} \)

\( \gamma_{rn} \)  
complex function of X in the solution of temperature variations in body with nonlinear radiation on front face

\( \omega_{n} \)  
argument rate in \( \gamma_{rn} \), rad/min

\( \omega \)  
argument rate in the expansion of heat rates on a spacecraft's surface, rad/min

\( \varepsilon \)  
total hemispherical emissivity

\( \hat{n} \)  
unit vector coinciding with the spin axis of the spacecraft

(\( \hat{\mathbf{p}}A \))  
unit vector coinciding with the axis of rotational symmetry of the spacecraft

(\( \hat{\mathbf{u}}_{\text{Sun}} \))  
unit vector coinciding with the satellite-sun line

(\( \hat{\mathbf{z}} \))  
unit vector coinciding with the satellite-earth line

Subscripts:

(\( _{m} \))  
mean value with respect to time

(\( _{\text{surf}, \text{mean}} \))  
mean surface value

(\( _{\text{surf}, \text{max}} \))  
maximum surface value

(\( _{\text{eq}} \))  
equilibrium condition
VI. ANALYSIS

A. Problem Definition

The study of the thermal control of spacecraft is a study of heat transfer, where the governing equation, expressed in vector notation is (see ref. 3)

\[ \nabla \cdot \mathbf{q} + p = \rho c \frac{\partial T}{\partial t} \]  

(1)

Here

- \( \nabla \) is the vector del operator
- \( p \) is the heat created in the material acting as a heat conductor
- \( \rho \) is the density of the material acting as a heat conductor
- \( c \) is the density of the material acting as a heat conductor
- \( T \) is the temperature of the material acting as a heat conductor
- \( t \) is time

\( \mathbf{q} \) is the heat flow vector

whose \( i \)th component is expressed as

\[ q_i = -K_i \frac{\partial T}{\partial x_i} \]

where

- \( K_i \) is the thermal conductivity in the \( i \)th direction
- \( x_i \) is the coordinate assigned to the \( i \)th direction

In many cases equation (1) cannot be solved without recourse to numerical techniques. Even when exact solutions to the equation are available,
many times the approximate solution will provide a more meaningful result. Thus as a beginning equation (1) will be specialized for several cases of particular interest.

A first important specialization will be to find an expression governing the space mean temperature for some segment of a spacecraft. This can be accomplished by integrating equation (1) over the body in question, or

\[ \nabla \cdot \vec{q} dA + \rho dA = \rho c \frac{\partial T}{\partial t} dA \]

where \( A \) represents the volume of the segment under study.

However, by use of the divergence theorem it is recognized that

\[ \nabla \cdot \vec{q} dA = -\vec{q} \cdot \vec{n} dS = 0 \quad \text{(not heat absorbed per unit time)} \]

\[ \rho dA = P \quad \text{(net heat created internally)} \]

and

\[ \rho c \frac{\partial T}{\partial t} dA = \rho c \frac{\partial}{\partial t} T dA = \rho c \frac{\partial}{\partial t} (T dA) \]

\[ = (\rho A) c \frac{\partial T}{\partial t} = mc \frac{\partial T}{\partial t} \]

where \( \vec{n} \) is the surface unit normal vector and the script \( T \) is
employed for

\[ \frac{1}{\lambda} \int_{\lambda} \nabla T_{\lambda} = T_{\lambda} \]

Thus the differential equation for \( T_{\lambda} \) is

\[ mc \frac{\partial T_{\lambda}}{\partial t} = p + \Phi \tag{2} \]

A second specialization to be considered is for the case of heat flow in a thin-walled body. In this case the heat flow vector (\( \vec{q} \)) can be separated into two components; one normal to the shell surface (\( \vec{q}_n \)) and the other tangent to the shell surface (\( \vec{q}_t \)), that is

\[ \vec{q} = \vec{q}_n + \vec{q}_t \]

Hence, equation (1) can be written as

\[ \nabla \cdot \vec{q}_n + \nabla \cdot \vec{q}_t + p = \rho c \frac{\partial T}{\partial t} \]

But, for thin shells

\[ \nabla \cdot \vec{q}_n = \left( \text{net } \frac{q_n}{r} \right) = \frac{q_n}{r} \]

where \( r \) is the shell wall thickness. Thus there follows

\[ \nabla \cdot \vec{q}_t + \frac{\vec{q}_n}{r} + p = \rho c \frac{\partial T}{\partial t} \tag{3} \]
Equation (3) is of particular importance since it approximates a three-dimensional problem by a much simpler two-dimensional problem. The power term, \( p \), is present only for those bodies where electrical currents are used; \( q_n \) is the power received per unit area on the body's external surfaces.

For a spacecraft in a near-earth orbit \( q_n \) is predominately due to the radiant power received from the sun; radiant power indirectly received from the sun (reflected by the earth onto the spacecraft (albedo)), and radiant power emitted by the earth. The calculation of \( q_n \) is straightforward and presents no theoretical difficulty; however, when conventional methods are applied to the problems encountered in thermal design of spacecraft, they become awkward.

Approximate methods of calculating \( q_n \) are presented in the next section.

B. Derivation of the Radiation Transfer Equation

The development of realistic techniques for calculating the heat flux on a spacecraft must begin with the well-known expression for the radiant power exchanged between two elemental areas radiating to each other. Text books on heat transfer are sometimes guilty of leading the reader to believe that thermal radiation is a surface property, thus an oversimplified model is presented to the reader. Consequently, the terms "diffuse" and "specular" radiation sometimes are only vaguely understood.

For these reasons a simplified derivation of the classical radiation heat-transfer equation is presented. Too, this derivation can
serve to define the terms appearing in the radiation heat-transfer equation. The pertinent geometry is shown in figure 1.

In figure 1, plane $P$ is considered to be an infinite plane containing the elemental area $(dA_1)$, which classically radiates heat to $(dA_2)$. The radiating material is bounded on its upper surface by plane $P$ but is considered to be infinite in extent on the lower bound. The radiated heat originates from $(dA_1 Y_0)$, the elemental volume immersed in the semi-infinite material.

The area $(dA_1)$ passes radiant heat from the elemental volume $(dA_1 Y_0)$ to the elemental area $(dA_2)$. The area $(dA_2)$ is chosen as perpendicular to the center line joining $dA_1$ to $dA_2$.

The radiating material itself radiates heat uniformly in all directions, from all self-contained points. However, $dA_1$ is so small it does not appreciably reabsorb its own radiated energy.

Let the power emitted (per unit volume) by $dA_1$ be $\phi_A$. This must be partially reabsorbed as the heat travels away from $(dA_1)$, otherwise the media could not radiate. Hence $\phi_A$ is not a constant, but

$$\phi_A = \phi_A(r) = \frac{4 \pi r^2 q_A(r)}$$

where $q_A(r)$ is the heat flux per unit area at a distance $r$ from its source.

There is no absorbing media between $dA_1$ and $dA_2$, hence all the heat from $dA_1$, flowing through $dA_2$, will reach $dA_2$. As a direct consequence of this statement
(\(R - R_1\))^2 q_\lambda(r = R - R_1) = (R)^2 q_\lambda(r = R)

or

\[q_\lambda(r = R) = \frac{(R - R_1)^2}{R^2} q_\lambda(r = R - R_1)\]

By applying the previous definitions

\[
d\phi_2 = \left(\frac{R - R_1}{R}\right)^2 q(R - R_1) d\lambda
\]

Here \(\phi_2\) is the total radiant power per unit area of \(dA_2\) incident on \(dA_2\) (from \(\Lambda\)) passing through \(dA_1\). Now according to the sketch

\[dA = dA_1 \left(\frac{R}{R_1}\right)^2\]

and

\[d\lambda = \cos \theta \, dR\]

Now, defining \(\phi_2\) as

\[\phi_2 = dA_2 \phi_2\]

then

\[d\phi_2 = dA_2 \left(\frac{R - R_1}{R}\right)^2 q_\lambda(r = R - R_1) dA_1 \left(\frac{R}{R_1}\right)^2 \cos \theta \, dR\]

and
Now set \((R - R_1) = x\), so that

\[
\phi_2 = \frac{dA_2 dA_1 \cos \theta}{R_1^2} \int_{R_1}^{\infty} (R - R_1)^2 q_1(r = R - R_1) \, dr
\]

Since this is a definite integral, then

\[
\phi_2 = c \frac{dA_2 dA_1 \cos \theta}{R_1^2}
\]

A simple integration shows that if \(J_1 dA_1\) is the total heat flowing through \(dA_1\) then \(c\) is simply \((J_1/x)\). Letting

\[
dA_2 = dA_{2,1}
\]

and

\[
dA_1 \cos \theta = dA_{1,2}
\]

where \(dA_{1,j}\) reads: the area that \(dA_1\) projects onto \(dA_j\), then

\[
\phi_2 = \frac{J_1 dA_2,1 dA_{1,2}}{x R_1^2}
\]

There will be no confusion if the subscript on \(R\) is dropped; then, in general, for two bodies \((i,j)\),
Provided that

\[ R^2 \gg dA_j \text{ or } dA_l \]

The above described radiation is said to radiate diffusely from \( dA_l \).

C. Calculation of Area Distributions

When equation (4) is employed for calculating the radiant power transferred from the earth to a spacecraft, the projected area of the spacecraft satisfies the condition that its dimensions are small in comparison to the distance between the earth and spacecraft. This thesis will consider spacecraft with external surfaces approximating simply joined (convexly arranged) cones aligned along an axis of rotational symmetry. The following preliminary remarks will clarify some spinning motions encountered by rotating spacecraft.

Near-earth satellites, which have passive temperature control, often spin about an axis of rotation. During last-stage coasting and burning of the booster, the spacecraft and the last-stage motor may be spun to achieve dynamic stability. At burnout the payload is injected into orbit with some residual spin. In the absence of strong external torques the spacecraft's angular momentum vector will approximately maintain a fixed direction relative to inertial space. If the spacecraft is not perfectly rigid some angular kinetic energy may be lost through structural vibrations, particularly if the spin axis is an axis other than that of the largest moment of inertia. Under this condition
the spacecraft's spin axis will transfer, in some finite lapse of time, to the axis having the largest moment of inertia. In this thesis it will be assumed that the initial spin axis is that of rotational geometrical symmetry and not the axis of largest moment of inertia. Initial spin will be referred to as the "short term spin mode;" the final spin mode will be referred to as the "long term spin mode."

For this reason the projected areas projections of the cone must be investigated for spin about an axis of geometrical symmetry and also for spin about an axis perpendicular to the axis of geometrical symmetry. It is tacitly assumed that intermediate spin modes are unimportant to the thermal design of a spacecraft.

Most spacecraft, whose external surfaces cannot be physically approximated by a series of cones, may be optically representable by a series of cones (if the spacecraft spins fast enough so that temperature fluctuations over one spin cycle can be neglected) for the purpose of calculating heat flux on the spacecraft.

In figure 2 $\mathrm{d}A_y$ is an elemental surface area for a cone of half angle $\delta$. The elemental area, $\mathrm{d}A_y$, is viewed along the unit vector $\vec{v}$, $\vec{n}$ is the unit normal vector of $\mathrm{d}A_y$. Thus

$$\mathrm{d}A_y = \frac{1}{2} r^2 \sin \delta \mathrm{d}\gamma$$

while

$$\vec{n} = \vec{e}_x_b (\cos \delta \cos \gamma) + \vec{e}_y_b (\cos \delta \sin \gamma) + \vec{e}_z_b (\sin \delta)$$

and
\[ \mathbf{\vec{v}} = \vec{e}_a (\sin \eta) + \vec{e}_b (\cos \eta) \]

where the \( \vec{e}_a \) and \( \vec{e}_b \) are unit vectors in the \( i \)th directions.

The projection of \( dA_v \) along \( \mathbf{\vec{v}} \) is

\[ dA_{v,\mathbf{\vec{v}}} = (\mathbf{\vec{v}} \cdot \mathbf{\vec{v}}) dA_v \]

so that the total area of the cone projected onto \( \mathbf{\vec{v}} \) is

\[ A_{v,\mathbf{\vec{v}}} = \bigcap_{v} (\mathbf{\vec{v}} \cdot \mathbf{\vec{v}}) dA_v \]  

Here the star superscript signifies that all negative values of \( (\mathbf{\vec{v}} \cdot \mathbf{\vec{v}}) \) are deleted from the integration. Thus, for the cone,

\[ A_{v,\mathbf{\vec{v}}} = 2 \left( \frac{l^2 \sin \theta}{2} \right)^{\gamma_0} \cos \theta \cos \gamma_0 \sin \eta + \sin \theta \cos \gamma_0 \sin \eta \]

where \( \gamma_0 \) is determined from

\[ \cos \delta \cos \gamma_0 \sin \eta + \sin \delta \cos \gamma_0 = 0 \]

which is possible if and only if

\[ |\cos \delta \sin \eta| \geq |\sin \delta \cos \gamma_0| \]
If this condition does not hold, then

\[ \gamma_0 = \pi \text{ if } \eta < \frac{\pi}{2} \]

\[ \gamma_0 = 0 \text{ if } \eta > \frac{\pi}{2} \]

If equation (6) does hold then \( \gamma_0 \) is given by

\[ \cos \gamma_0 = -\tan \delta \cot \eta \]

and

\[ A_{\nu,\nu} (\eta) = r^2 \sin \delta \left( (\cos \delta \sin \gamma_0) \sin \eta + (\gamma_0 \sin \delta) \cos \eta \right) \]

Now, the total lateral area of the cone is

\[ A_v = \pi r^2 \sin \delta \]

and hence the normalized area distribution for the cone is simply

\[ \mu_v (\eta) = \frac{A_{\nu,\nu} (\eta)}{A_v} = \frac{1}{\pi} \left( (\cos \delta \sin \gamma_0) \sin \eta + (\gamma_0 \sin \delta) \cos \eta \right) \]

providing for the well-known special cases of

\[ \mu_v (\eta) = \frac{1}{\pi} \sin \eta \quad (\text{cylinder, } \delta = 0) \]

and

\[ \mu_v (\eta) = \cos^\ast \eta \quad (\text{flat plate, } \delta = \pi/2) \]

The other case of interest is the average area projected to the viewer along \( \tilde{v} \), by the cone, as it rotates (one revolution) about an axis perpendicular to the axis of symmetry. If this projection is denoted by \( \tilde{\beta}(\eta) \), then
\[ n_v = \left(\frac{1}{4\pi}\right) \int_0^{2\pi} n_v(\vartheta, \xi) d\xi \]  

where \( \vartheta \) locates the viewer relative to the spin axis; \( \xi \) is the angle of rotation, and \( \vartheta_1 \) is the angle from \( \tilde{v} \) to \( \tilde{v}_1 \) (PA). Figure 3 shows the relation between \( \vartheta, \vartheta_1 \), and \( \xi \).

**Example of conical projected areas.**—A right circular cone of half angle \( \beta \), and having a unit surface area, has been chosen to demonstrate these solutions. The projected area of the cone in both spin modes, spinning about its axis of symmetry and about an axis perpendicular to the axis of symmetry, has been calculated for cone half angles of \( 0^\circ \), \( 22.5^\circ \), \( 45^\circ \), \( 67.5^\circ \), and \( 90^\circ \). The results, \( n(\vartheta) \) and \( \hat{n}(\vartheta) \), are plotted in figures 13(a) and 13(b).

**D. Calculation of Albedo and Earth Thermal Heating**

Although the calculation of earth thermal and reflected solar (albedo) power is straightforward, the complete compilation of such data for arbitrarily shaped bodies would be a gigantic task even for modern digital computers. For this reason several series solutions will be developed. These can be truncated to produce simple and accurate approximations for both earth thermal and albedo heating, of an arbitrary shaped spacecraft, provided the spacecraft sees no shaded area on the earth.

In figure 4 a spherical coordinate frame is shown which is centered in the spacecraft. The \( Z \) axis is the polar axis and \( \gamma \) the azimuth angle of \( \tilde{v} \) (the unit vector that points to that elemental area on the
The polar angle of \( \tilde{v} \) that is, \( \omega_c \) is the angle between the earth-satellite line and \( \tilde{v} \), here the \( \tilde{F} \) axis coincides with the earth-satellite line. In this coordinate frame equation (4), after integration, yields

\[
\Phi_{1,v} = \left( \frac{A_y}{\pi} \right) \int_S \psi_{1,y}(\cdot) \sin \theta \, d\theta dy
\]  

(9)

The subscript \( i \) denotes the origin of the radiation and \( v \) denotes the receiver of the radiation.

For the case of earth thermal radiation \( J_e \) is commonly assumed to be constant. For the albedo \( J_a \) is, from reference 1,

\[
J_a = 3r_e \cos^2 \beta \sin \theta
\]

where

- \( r_e \) is the percent of the thermal energy (from the sun and incident on the earth) which is reflected by the earth
- \( S \) is the solar constant
- \( \beta \) is the incidence angle of the sun's light on the earth's local surface

Under the restrictions for which \( \mu(\eta) \) and \( \hat{\mu}(\eta) \) were developed both are even functions of \( \eta \) and may be represented by a cosine series, or
\[ \mu(\eta) = \sum_{i=1} c_1 \cos i \eta \]

\[ \hat{\mu}(\eta) = \sum_{i=1} \hat{c}_1 \cos i \eta \]

With these conventions equation (9) becomes, after interchanging order of summation with integration,

\[ \theta_{i,v} = \frac{\theta A v}{A v} = \frac{1}{2} \sum_{k} c_k \int_{S} J_1 \cos k \eta \sin \theta d\theta d\gamma \quad (10) \]

From figure (4) it is evident that

\[ \bar{z} = \bar{e}_{x_b}(\sin \eta_c) + e_{z_b}(\cos \eta_c) \]

and

\[ \bar{v} = \bar{e}_{x_b}(\sin \theta \cos \gamma) + \bar{e}_{y_b}(\sin \theta \sin \gamma) + e_{z_b}(\cos \theta) \]

hence

\[ \cos \eta = \bar{z} \cdot \bar{v} = \cos \eta_c \cos \theta + \sin \eta_c \sin \theta \cos \gamma \quad (11) \]

The geometry defining \( J_a \) is shown in figure 5. In the sketch the \( (X_b, Y_b, Z_b) \) coordinate frame has been translated along \( Z_b \) a distance \( R_T \) (the distance from the satellite's center to the earth's center) to facilitate definition of the angles shown in the sketch.
The $x_0, y_0, z_0$ reference frame in this sketch is the same as the $x_b, y_b, z_b$ coordinate frame described previously. The angles shown are defined from the sketch proper. The law of cosines, from spherical trigonometry, expresses the angle $\beta_0$ as

$$\cos \beta_0 = \cos R_e \cos \beta + \sin R_e \sin \beta \cos(\gamma + \gamma_0)$$

and the angle $(\gamma)$ is the $\gamma$ in equation (9). An expression relating $\theta$ and $\beta$ can be written from the geometry of figure 5, namely,

$$R_T = R_e \cos \beta + R \cos \theta$$

(12)

But according to the law of sines

$$\frac{R}{\sin \beta} = \frac{R_e}{\sin \theta} \quad \text{and} \quad \sin \theta_0 = \left(\frac{R_e}{R_T}\right)$$

These relations can be combined to yield

$$\sin \theta = \sin \theta_0 \sin(\theta + \beta)$$

which reduces to

$$\sin \theta = \left(\frac{\sin \theta}{\sin \theta_0}\right) \left(\cos \theta - \left[\sin^2 \theta_0 - \sin^2\theta\right]^{1/2}\right)$$

(13)

and

$$\cos \beta = \left(\frac{\sin \theta}{\sin \theta_0}\right) \left(\sin \theta + \cot \theta \left[\sin^2 \theta_0 - \sin^2\theta\right]^{1/2}\right)$$

(14)

Equations (11), (13), and (14) express all the variables in equation (10) in terms of the variables of integration, $\theta$ and $\gamma$. 

Thus for the albedo heat, through an accuracy of \( \cos \theta \), is

\[
\phi_{a,v} \approx \left( \frac{S_r e}{\pi} \right) c_0 \int_{S} \{ \cos \beta_n \} \sin \theta d\theta d\gamma \\
+ \left( \frac{S_r e}{\pi} \right) c_1 \int_{S} \{ \cos \beta_n \cos \gamma \} \sin \theta d\theta d\gamma \\
+ \left( \frac{S_r e}{\pi} \right) c_2 \int_{S} \{ \cos \beta_n \cos 2\gamma \} \sin \theta d\theta d\gamma \\
+ \left( \frac{S_r e}{\pi} \right) c_3 \int_{S} \{ \cos \beta_n \cos 3\gamma \} \sin \theta d\theta d\gamma \\
+ \left( \frac{S_r e}{\pi} \right) c_4 \int_{S} \{ \cos \beta_n \cos 4\gamma \} \sin \theta d\theta d\gamma
\]

The integration for \( \gamma \) may be carried out immediately, leaving only the integration with respect to \( \theta \) to be provided. The resulting expression may be divided into even and odd functions of \( B_5 \), or

\[
\phi_{a,v} \approx S_r \{ G_1(\theta_0, \eta_e) \cos \gamma_0 \sin B_5 \\
+ G_2(\theta_0, \eta_e) \cos B_5 \}
\]

(15)

where

\[
G_1(\theta_0, \eta_e) = \left\{ c_1 \left[ \sin \eta_e \right] F_{11}(\theta_0) \right\} + c_2 \left\{ 4 \left[ \cos \eta_e \sin \eta_e \right] F_{23}(\theta_0) \right\} \\
+ c_3 \left\{ 12 \left[ \cos^2 \eta_e \sin \eta_e \right] F_{32}(\theta_0) + 3 \left[ \sin^3 \eta_e \right] F_{33}(\theta_0) \right\} \\
- 3 \left[ \sin \eta_e \right] F_{35}(\theta_0) + c_4 \left\{ 32 \left[ \cos^3 \eta_e \sin \eta_e \right] F_{46}(\theta_0) \right\} \\
+ 24 \left[ \cos \eta_e \sin^3 \eta_e \right] F_{47}(\theta_0) - 16 \left[ \cos \eta_e \sin \eta_c \right] F_{48}(\theta_0) \right\}
\]
and

\[ c_2(\theta_0, \eta_e) = c_0 \left( 2F_{00}(\theta_0) \right) + c_1 \left( 2\left[ \cos \eta_e \right] F_{10}(\theta_0) \right) + c_2 \left( 4\left[ \cos^2 \eta_e \right] F_{20}(\theta_0) + 2\left[ \sin \eta_e \right] F_{21}(\theta_0) - 2F_{22}(\theta_0) \right) + c_3 \left( 8\left[ \cos^3 \eta_e \right] F_{30}(\theta_0) + 12\left[ \cos \eta_e \sin^2 \eta_e \right] F_{31}(\theta_0) + 6\left[ \cos \eta_e \right] F_{32} \right) + c_4 \left( 16\left[ \cos^4 \eta_e \right] F_{40}(\theta_0) + 48\left[ \cos^2 \eta_e \sin^2 \eta_e \right] F_{41}(\theta_0) + 6\left[ \sin \eta_e \right] F_{42}(\theta_0) - 16\left[ \cos \eta_e \right] F_{43}(\theta_0) + 8\left[ \sin \eta_e \right] F_{44}(\theta_0) + 2F_{45}(\theta_0) \right) \]

The \( F_{1k} \)'s are expressible in terms of elementary functions; however, for this thesis they have been numerically integrated and are given on table 1. In particular, the \( F_{1k} \)'s are given by

\[ F_{00}(\theta_0) = F_{45}(\theta_0) = F_{22}(\theta_0) = \int_0^{\theta_0} \left\{ \cos \beta + \right\} \sin \delta \theta \]

\[ F_{10}(\theta_0) = F_{34}(\theta_0) = \int_0^{\theta_0} \left\{ \cos \beta \cos \theta \right\} \sin \delta \theta \]

\[ F_{11}(\theta_0) = F_{35}(\theta_0) = \int_0^{\theta_0} \left\{ \sin \beta \sin \theta \right\} \sin \delta \theta \]
\[ F_{20}(\theta_0) = F_{43}(\theta_0) = \int_0^{\theta_0} \{\cos \beta \cos^2 \theta\} \sin \theta d\theta \]

\[ F_{21}(\theta_0) = F_{44}(\theta_0) = \int_0^{\theta_0} \{\cos \beta \sin^2 \theta\} \sin \theta d\theta \]

\[ F_{23}(\theta_0) = F_{46}(\theta_0) = \int_0^{\theta_0} \{\sin \beta \cos \theta \sin \theta\} \sin \theta d\theta \]

\[ F_{30}(\theta_0) = \int_0^{\theta_0} \{\cos \beta \cos^3 \theta\} \sin \theta d\theta \]

\[ F_{31}(\theta_0) = \int_0^{\theta_0} \{\cos \beta \cos \theta \sin^2 \theta\} \sin \theta d\theta \]

\[ F_{32}(\theta_0) = \int_0^{\theta_0} \{\sin \beta \cos^2 \theta \sin \theta\} \sin \theta d\theta \]

\[ F_{33}(\theta_0) = \int_0^{\theta_0} \{\sin \beta \sin \theta\} \sin \theta d\theta \]

\[ F_{40}(\theta_0) = \int_0^{\theta_0} \{\cos \beta \cos^4 \theta\} \sin \theta d\theta \]
\[ F_{41}(\theta_0) = \int_0^{\theta_0} \left\{ \cos \beta \cos^2 \vartheta \sin^2 \varphi \right\} \sin \vartheta \, d\vartheta \]

\[ F_{42}(\theta_0) = \int_0^{\theta_0} \left\{ \cos \beta \sin^4 \varphi \right\} \sin \vartheta \, d\vartheta \]

\[ F_{46}(\theta_0) = \int_0^{\theta_0} \left\{ \sin \beta \cos^3 \vartheta \sin \varphi \right\} \sin \vartheta \, d\vartheta \]

and

\[ F_{47}(\theta_0) = \int_0^{\theta_0} \left\{ \sin \beta \cos \vartheta \sin^3 \varphi \right\} \sin \vartheta \, d\vartheta \]

For the case of earth thermal radiation the integration of equation (9) yields

\[ \phi_e, \varphi = (\tau_T \beta) \varphi_3(\theta_0, \eta_e) \]

where

\[ \varphi_3(\theta_0, \eta_e) = C_0 \left\{ 2(1 - \cos \theta_0) \right\} + C_1 \left\{ \cos \eta_e \sin^2 \theta_0 \right\} \]

\[ + C_2 \left\{ \frac{2}{3} \left[ \cos^2 \eta_e \right] (1 - \cos \theta_0) + \frac{1}{3} \left[ \sin^2 \eta_e \right] (2 - \cos \theta_0 \sin^2 \theta_0) - 2 \cos \theta_0 \right\} + C_3 \left\{ \frac{1}{2} \left[ \cos^3 \eta_e \right] (1 - \cos \theta_0) \right\} \]

\[ + \frac{3}{4} \left[ \cos \eta_e \sin^2 \eta_e \right] (\sin \theta_0) \right\} + C_4 \left\{ \frac{2}{3} \left[ \cos^4 \eta_e \right] (1 - \cos \theta_0) \right\} \]

\[ + \frac{1}{20} \left[ \sin^4 \eta_e \right] (3 - 3 \sin^2 \theta_0 \cos \theta_0 - 4 \cos \theta_0 \sin^2 \theta_0 - 3 \cos \theta_0) \]

\[ + \frac{6}{5} \left[ \sin^2 \eta_e \cos \eta_e \right] \left[ \frac{2}{3} - \cos^3 \theta_0 \sin^2 \theta_0 - \frac{2}{3} \cos^3 \theta_0 \right] \]
and where

\[ c_0 = c_0 - c_2 + c_4 \]
\[ c_1 = c_1 - 3c_3 \]
\[ c_2 = 2c_2 - 6c_4 \]
\[ c_3 = 4c_3 \]
\[ c_4 = 8c_4 \]

example of albedo and earth thermal radiation. As an example of albedo and earth thermal radiation, let a flat plate of unit area be irradiated on one exposed side. The relevant geometry is shown in figure 6.

Through an accuracy of \( \cos \theta \)

\[ \mu(\theta) \approx c_0 + c_1 \cos \theta + c_2 \cos 2\theta + c_4 \cos 4\theta \]

where

\[ c_0 = \frac{1}{\pi} \approx 0.3185 \]
\[ c_1 = \frac{1}{2} = 0.5000 \]
\[ c_2 = \frac{2}{3\pi} \approx 0.2122 \]
\[ c_4 = -\frac{2}{15\pi} \approx -0.0424 \]

The angle \( \theta_0 \) was chosen as \( 60^\circ \), hence the proper values of the pertinent \( F_{1, f} \), from table 1, are
When these numbers are introduced into the defining equation for \( G_1, G_2 \) and \( G_3 \), it is found that

\[
G_1 = 0.0297 \sin \eta_e + 0.0533 \sin \eta_e \cos \eta_e - 0.0233 \sin \eta_e \cos^3 \eta_e
- 0.0213 \cos \eta_e \sin^3 \eta_e
\]

\[
G_2 = 0.217 + 0.369 \cos \eta_e + 0.285 \cos^2 \eta_e - 0.195 \sin^2 \eta_e \cos^2 \eta_e
- 0.130 \cos^4 \eta_e - 0.0270 \sin^4 \eta_e
\]

and

\[
G_3 = 0.2228 + 0.3749 \cos \eta_e + 0.2663 \cos^2 \eta_e - 0.1993 \cos^2 \eta_e \sin^2 \eta_e
- 0.1314 \cos^4 \eta_e - 0.0261 \sin^4 \eta_e
\]

The close agreement between \( G_2 \) and \( G_3 \) is striking, while \( G_1 \) is small and an odd function of \( \eta_e \). These solutions are plotted on figures 14(a) and 14(b).

It is easily understood that as \( \theta_0 \) increases, the close agreement between \( G_2 \) and \( G_3 \) increases. Thus for the \( \theta_0 \) value used here, or for larger values the so-called "shape factors" for earth thermal and albedo heating are nearly the same provided the intensity of the albedo \( (J_a) \) is taken from the satellite's subpoint and provided the spacecraft does not see past the earth's terminator.
At this point a discussion of the assumptions used in calculating the albedo and earth thermal radiations is in order.

When equation (9) is used to calculate the earth's thermal power, incident on a spacecraft, the assumption is usually made that $J_e$ is constant. When one considers that the earth's surface may easily vary from 570° R, at the earth equatorial regions, to 460° R at the earth's polar region, it is clear that $J_e$ could easily vary by as much as 50 percent of its maximum value. It would be difficult to obtain very accurate results with such an assumption; however, the only alternative is to construct some type of $J_e$ map (for the earth). Unfortunately there are few if any of these in existence. For the present (then) the thermal designer should choose $J_e$ as a constant.

Clearly the representation of $\mu(\eta)$ in a Fourier cosine series, for this case, must be acceptable since a termination of the series after cos $4\eta$ will introduce only about a 4-percent error over the maximum amplitude for a flat plate, which is (in a sense) an extreme case.

For illustrative purposes $\cos^4 \eta$ versus $\eta$ through terms of $\cos 4\eta$ is plotted in figure 20(a). In figure 20(b) the resulting $G_3(\eta_e)$ values, for heights above the earth's surface of 0 and 392 nautical miles, are plotted. The values of $G_3(\eta_e)/(G_3)_{\text{max}}$ evaluated for an infinite height above the earth's surface, where $\mu(\eta)$ has been terminated after cos $4\eta$, is plotted in figure 20(a). The corresponding exact solution for $G_3(\eta_e)/(G_3)_{\text{max}}$ is plotted in figure 20(b). It should be noted here that $G_3(\eta_e)$ gives $\delta_e$ for a body of any shape if multiple
light reflections are negligible and if the body spins about some axis with sufficient speed so that only small changes in temperature occur during one complete revolution. Otherwise, the body shape must conform to a rotational symmetry about one particular axis. Other properties of $\phi_c$ will be discussed later.

The calculation of $\phi_a$ is dependent upon the many factors shown in equation (15). In the development of $\phi_a$ it was assumed that the surface of the earth was a uniform diffusely reflecting sphere. The manner in which the earth, and its atmosphere, scatter and reflect sunlight is quite complex; however, it is suggested in reference 7 that the earth's albedo might vary between 32 percent and 52 percent. A large portion of the albedo is due to cloud cover which may or may not be uniformly distributed over the earth's surface. Thus it is evident that there is some futility in attempting an exact solution for $\phi_a$. With this difficulty in mind it appears that the series approximation for $\mu(\eta)$, for purposes of calculating $\phi_a$, is more than sufficient.

The calculation of $\phi_a$, using equation (15), also has the advantage of simplicity and versatility that was found in the calculation of $\phi_c$ by the same process. There is one big failing attached to equation (15) since in its development the assumption was made that $\cos \beta$ was always positive. This assumption fails when the spacecraft approaches the earth's terminator; here $\cos \beta$ is zero on the terminator and the portion of the earth's surface which is shielded from the sun has a negative value for $\cos \beta$. Since these negative values were not deleted from the integration, $\phi_a$ as described by equation (15), is in error.
The precise size of this error can only be determined by an exact solution of equation (9). However, it is clear that when equation (15) is in error, the albedo heat is considerably decreased from its maximum value (at $B_s = 0$). Also assuming the albedo ($r_e$) constant can introduce more error into the $\Phi_a$ calculation than the error caused by including negative values of $\cos \beta_c$ in the $\Phi_a$ calculation. (The latter results in values of $\Phi_a$ less than the exact $\Phi_a$ solutions.)

As was mentioned, the odd part of $\Phi_a$ is small compared to the even part; use of the odd part requires the determination of $\gamma_0$ which is no simple matter. If the odd part of $\Phi_a$ is neglected, and only the even part used, figure 14(a) shows that $G_2$ is slightly larger than the even part of $\Phi_a$. Thus if $G_2$ is used in place of $\Phi_a$ there is a compensating effect for the error incurred by including negative values of $\cos \beta_c$ in the calculation of $\Phi_a$.

For these reasons $G_3(\psi_e, \theta_0)$ is used in place of $G_2(\psi_e, \theta_0)$ in this thesis. One should also remember that $G_3(\psi_e, \theta_0)$ is much simpler to use in the analytical studies.

E. Calculation of Orientation Angles

The preceding developments can be used to calculate the radiant power incident on a space-craft's external surface as a function of the angles

$\psi_e, \psi_b, B_s, \theta_0, \gamma_0$

These angles may be found as follows:
Erect a nonrotating cartesian coordinate frame centered at the earth's center. In figure 7, the Z axis coincides with the earth's north pole and the Y axis is perpendicular to the earth-sun line at the summer solstice. Now rotate the axis system about the Z axis, through angle $\phi_{AN}$, until the X axis pierces the ascending node; now the $(X,Y,Z)$ frame coincides with the $(X_1,Y_1,Z_1)$ frame. Next provide a rotation about the $X_1$ axis, through the angle I, until the Y axis lies in the orbit plane; the $(X,Y,Z)$ frame coincides with the $(X_2,Y_2,Z_2)$ frame. Finally a rotation about the $Z_2$ axis, through the angle E is provided, so that the X axis passes through the satellite and the $(X,Y,Z)$ frame coincides with the $(X',Y',Z')$ frame. The coordinates of any point $P(X',Y',Z')$ may be calculated from $P(X,Y,Z)$ by the coordinate transformation, or

$$
\begin{pmatrix}
X' \\
Y' \\
Z'
\end{pmatrix} = Q(E)Q(I)Q(\phi_{AN})
\begin{pmatrix}
X \\
Y \\
Z
\end{pmatrix}
$$

where

$$Q(\phi_{AN}) = 
\begin{bmatrix}
\cos \phi_{AN} & \sin \phi_{AN} & 0 \\
-sin \phi_{AN} & \cos \phi_{AN} & 0 \\
0 & 0 & 1
\end{bmatrix}
$$

$$Q(I) = 
\begin{bmatrix}
1 & 0 & 0 \\
0 & \cos I & \sin I \\
0 & -\sin I & \cos I
\end{bmatrix}
$$

and
\[
\mathbf{Q}(E) = \begin{bmatrix}
\cos E & \sin E & 0 \\
\sin E & \cos E & 0 \\
0 & 0 & 1
\end{bmatrix}
\]

On carrying out the indicated multiplication

\[
\mathbf{q}(E)\mathbf{q}(I)\mathbf{q}(\phi_{AN}) = \mathbf{q}
\]

is a matrix whose elements are

\[
\begin{align*}
Q_{11} &= \cos E \cos \phi_{AN} - \sin E \cos I \sin \phi_{AN} \\
Q_{12} &= \cos E \sin \phi_{AN} + \sin E \cos I \cos \phi_{AN} \\
Q_{13} &= \sin E \sin I \\
Q_{21} &= -\sin E \cos \phi_{AN} - \cos E \cos I \sin \phi_{AN} \\
Q_{22} &= -\sin E \sin \phi_{AN} + \cos E \cos I \cos \phi_{AN} \\
Q_{23} &= \cos E \sin I \\
Q_{31} &= \sin I \sin \phi_{AN} \\
Q_{32} &= -\sin I \cos \phi_{AN} \\
Q_{33} &= \cos I
\end{align*}
\]

Here, the symbol \([\ ]\) denotes a square matrix while \(\{\}\) denotes a column matrix.

To locate the position of the sun relative to the earth start again with the earth centered \((X,Y,Z)\) coordinate frame. (See fig. 8.)
First the axes are rotated about the Y axis, through angle $i$ until the X axis points to the sun at the summer solstice. In this position the $(X,Y,Z)$ frame coincides with the $(X_3,Y_3,Z_3)$ frame. Next give a rotation about the $Z_3$ axis, through angle $\Omega$, until the X axis points to the sun and the $(X,Y,Z)$ frame coincides with the $(X'',Y'',Z'')$ frame. Proceeding as in the previous case, then

$$\begin{pmatrix} X'' \\ Y'' \\ Z'' \end{pmatrix} = Q(\Omega)Q(i) \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}$$

where

$$Q(\Omega) = \begin{bmatrix} \cos \Omega & \sin \Omega & 0 \\ -\sin \Omega & \cos \Omega & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$Q(i) = \begin{bmatrix} \cos i & 0 & \sin i \\ 0 & 1 & 0 \\ -\sin i & \cos i & 0 \end{bmatrix}$$

and

$$Q(\Omega)Q(i) = \begin{bmatrix} \cos \Omega \cos i & \sin \Omega \cos \Omega \sin i \\ -\sin \Omega \cos i & \cos \Omega -\sin \Omega \sin i \\ -\sin i & 0 & \cos i \end{bmatrix}$$
In this thesis it will be assumed that the spacecraft's angular momentum vector lies in its orbit plane and is tangent to the local horizon at perigee. Too, it is assumed that the spacecraft is initially injected into orbit at its perigee position. It follows, then, that the $Y'$ axis coincides with the satellite's angular momentum vector when the satellite is initially injected into orbit, thus

$$\tilde{e}_H = \tilde{e}_{Y'}(0) \text{ where } \tilde{e}_{Y'} = \tilde{e}_{Y'}(t)$$

From this it follows that

$$\cos \eta_e = -[\tilde{e}_{Y'}(0)] \cdot [\tilde{e}_{X'}(t)]; \quad 0 \leq \eta_e \leq \pi$$

$$\cos \eta_B = [\tilde{e}_{Y'}(0)] \cdot [\tilde{e}_{X'}(t)]; \quad 0 \leq \eta_B \leq \pi$$

$$\cos \beta_B = \{[\tilde{e}_{X'}(t)] \cdot [\tilde{e}_{X'}(t)]; \quad 0 \leq \beta_B \leq 2\pi\}$$

Now, by the matrix transformation performed previously these equations may be written explicitly as

$$-\cos \eta_e = \left[ \left( -\sin \lambda_0 \cos \phi_0 - \cos \lambda_0 \cos I \cos \phi_0 \right) \cos E \cos \phi_{AN} \right.$$

$$\left. - \sin E \cos I \sin \phi_{AN} \right] + \left[ \left( -\sin \lambda_0 \sin \phi_0 \right. \right.$$

$$\left. + \cos \lambda_0 \cos I \cos \phi_0 \left( \cos E \sin \phi_{AN} + \sin E \cos I \cos \phi_{AN} \right) \right]$$

$$+ \left[ \left( \cos \lambda_0 \sin I \right) \left( \sin E \sin I \right) \right]$$

(16)
\[ \cos \eta_C = \left[ (-\sin \lambda_0 \cos \phi_0 - \cos \lambda_0 \cos I \sin \phi_0)(\cos \Omega \cos i) \right] \\
+ \left[ (-\sin \lambda_0 \sin \phi_0 + \cos \lambda_0 \cos I \cos \phi_0)(\sin \Omega) \right] \\
+ \left[ (\cos \lambda_0 \sin I)(\cos \Omega \sin i) \right] \tag{17} \]

and

\[ \cos B_C = \left[ (\cos E \cos \phi_{AN} - \sin E \cos I \sin \phi_{AN})(\cos \Omega \cos i) \right] \\
+ \left[ (\cos E \sin \phi_{AN} + \sin E \cos I \cos \phi_{AN})(\sin \Omega) \right] \\
+ \left[ (\sin E \sin I)(\cos \Omega \sin i) \right] \tag{18} \]

where

\[ \phi_{AN} = \phi_0 + \dot{\phi} \Delta t \]
\[ \lambda = \lambda_0 + \dot{\lambda} \Delta t; \ E = \delta + \lambda \]
\[ \Omega = \Omega_0 + \Delta \Omega \]

Here the subscript zero denotes initial conditions and the quantities \( \dot{\phi} \) and \( \dot{\lambda} \) may be calculated from reference 2. \( \Delta \Omega \) is the angular displacement of the earth about the sun, with \( \Delta \Omega \) equal to zero when \( \Delta t \) is zero. \( \delta \) is the spacecraft's angular position in orbit measured from the perigee.

The orientation quantities already calculated in this section are expressed in terms of the inertial coordinate frame \((X,Y,Z)\). Such a
coordinate system does not lend itself well to mental visualization; that is to say, equations (16), (17), and (18), in their present form, are just so many confusing expressions. The true character of these relations becomes clearer when the \((X'_0,Y'_0,Z'_0)\) coordinates are used. The \((X'_0,Y'_0,Z'_0)\) coordinates are those which coincide with the \((X',Y',Z')\) coordinates when the \(X'\) axis passes through the perigee position. However, it should be noted that this reference frame (the \((X'_0,Y'_0,Z'_0)\) coordinates) loses most of its mathematical utility because it (the \((X'_0,Y'_0,Z'_0)\) coordinate frame) is not fixed in inertial space. From figure 9 the required unit vectors can be expressed by

\[
\tilde{e}_x = \tilde{e}_{X'_0}(\cos \epsilon \cos \zeta) + \tilde{e}_{Y'_0}(\cos \epsilon \sin \zeta) + \tilde{e}_{Z'_0}(\sin \epsilon)
\]

\[
\tilde{e}_y = \tilde{e}_{X'_0}(\cos \nu \sin \psi) + \tilde{e}_{Y'_0}(\cos \nu \cos \psi) + \tilde{e}_{Z'_0}(\sin \nu)
\]

and

\[
\tilde{e}_z = \tilde{e}_{X'_0}(\cos \psi) + \tilde{e}_{Y'_0}(\sin \psi)
\]

After applying the definitions for \(\eta_e\), \(\eta_g\), and \(B_c\) the above expressions yield

\[
\cos \eta_e = -\cos \nu \sin(\delta + \psi) \tag{19}
\]

\[
\cos \eta_g = \cos \epsilon \cos \nu \sin(\zeta + \psi) + \sin \epsilon \sin \nu \tag{20}
\]

and

\[
\cos B_c = \cos \epsilon \cos(\delta - \zeta) \tag{21}
\]
The angles $\zeta$, $\hat{\nu}$, $\psi$, and $\epsilon$ can be found by comparing equations (19) through (21) with equations (15) through (18). Here the quantities are defined as

$\epsilon$ angle between sun and orbit plane

$\zeta$ angle between sun's projection onto orbit plane and perigee radius vector

$\hat{\nu}$ angle between orbit plane and spacecraft's angular momentum vector

$\psi$ angle between the spacecraft's angular momentum vector projection onto the orbit plane and the local earth horizon as the spacecraft passes through perigee

Now, $\gamma_0$, the angle between the (satellite momentum vector-satellite earth line) plane and the (sun earth line-satellite earth line) plane is defined by

$$\cos \gamma_0 = + \frac{\tilde{e}_y'(0) \times \tilde{e}_x'}{|\tilde{e}_y'(0) \times \tilde{e}_x'|} \cdot \frac{\tilde{e}_x'' \times \tilde{e}_x'}{|\tilde{e}_x'' \times \tilde{e}_x'|}$$

which, after inserting the definitions of the unit vectors, and after some reduction, becomes

$$\cos \gamma_0 = + \frac{\sin \hat{\nu} \sin \epsilon + \cos \hat{\nu} \cos \epsilon \cos(\delta + \gamma) \sin(\delta - \zeta)}{\left[ \sin^2 \epsilon + \cos^2 \epsilon \sin^2(\delta - \zeta) \right]^{1/2} \left[ \sin^2 \hat{\nu} + \cos^2 \hat{\nu} \cos^2(\gamma + \delta) \right]^{1/2}}$$

(22)

Thus the angles which determine the heat flux in equations (1), (2), and (3) are calculated.
F. Specialization of the Heat Equation to Spacecraft Problems

Consider a spacecraft in a near-earth orbit receiving direct solar energy, earth thermal energy, and albedo energy. Assume its external surfaces are composed of simply joined cones, cylinders, and flat plates.

It should be recognized that for many spacecraft it is impractical to calculate exact solutions for equation (1). And, when an average temperature over a section of the spacecraft is sufficient, equation (2) might be solved with much less computational effort. Equation (2) is

\[(mc) \frac{dT_i}{dt} = \Phi_i + P_i\]

here the subscript \(i\) denotes the section for which the equation is written; \(\Phi_i\) is the heat flux absorbed onto the \(i\)th surface; and \(P_i\) is the power generated internally and applied to the \(i\)th section. If some other section \(j\) of the spacecraft conducts heat to the \(i\)th section this heat transfer can be calculated from

\[\Phi_{ji} = h_{ji}(T_j - T_i)\]

If radiative heat transfer occurs between the \(j\)th and \(i\)th sections it can be calculated by

\[\Phi_{ji} = R_{ji}(T_j^4 - T_i^4)\]

where

\[T_i^h = \frac{1}{A_i} \int T_i^h dA_i\]
The power to the ith section, from external sources, is

\[ \Phi_i = S A_i s a_{e,i} + A_i \Phi_{a,i} a_{a,i} + A_i \Phi_{e,i} a_{e,i} - A_i \Sigma_i \sigma T_i^4 \]

where

- \( a_{e,i} \) percentage of solar radiation falling on \( i \) and which is absorbed
- \( a_{a,i} \) percentage of \( \Phi_{a,i} \) absorbed
- \( a_{e,i} \) percentage of \( \Phi_{e,i} \) absorbed
- \( \Sigma_i \) total hemispherical emissivity of the ith body section

When equation (2) is fully expanded it is

\[
(mc)_i \frac{dT_i}{dt} = P_i + S A_i s a_{e,i} + A_i \Phi_{a,i} a_{a,i} + A_i \Phi_{e,i} a_{e,i} - A_i \Sigma_i \sigma T_i^4
\]

\[ + \sum_{j=1}^{N} h_{ij}(T_i - T_j) + \sum_{j=1}^{N} R_{ij}(T_j - T_i) \quad \text{(23)} \]

In the literature an assumption commonly made is that the sun's energy spectrum is not significantly altered by the earth's scattering and reflection processes, hence

\[ a_{e,i} \sim a_{a,i} \]

also it is commonly assumed (in the literature) that

\[ a_{e,i} \sim \Sigma_i \]

This follows from the fact that most spacecraft are always near to the earth's surface temperature.
It should be noted that in equation (23)

\[ T_1^4 \neq T_1^4 \]

To see this difference let

\[ T = T_\Lambda + v \]

from which

\[ T^4 = T_\Lambda^4 + 4T_\Lambda^3v + 6T_\Lambda^2v^2 + 4T_\Lambda v^3 + v^4 \]

so that

\[ T_1^4 = \frac{1}{M_1} \int_{\Lambda_1} \left( T_\Lambda^4 + 4T_\Lambda^3v + 6T_\Lambda^2v^2 + 4T_\Lambda v^3 + v^4 \right) d\Lambda_1 \tag{23a} \]

But, since

\[ T_\Lambda = \frac{1}{M_1} \int_{\Lambda_1} T_1 d\Lambda_1 = \frac{1}{M_1} \int_{\Lambda_1} \left( T_\Lambda + v_1 \right) d\Lambda_1 = T_\Lambda + \frac{1}{M_1} \int_{\Lambda_1} v_1 d\Lambda_1 \]

then

\[ \int_{\Lambda_1} v_1 d\Lambda_1 = 0 \]

which implies that

\[ (v_1)^3 d\Lambda_1 \]

is small.

If \( v_1 \) is much less than \( T_\Lambda \) then the last term in equation (23a) is small compared to
then
\[ \frac{\delta T_A^2}{\Lambda_1} \sim \lambda_A^2 \left( (v_1)^2 d \Lambda_1 = 6T_A^2 v_1^2 \right) \]

so by the binomial expansion theorem,
\[ \sqrt[\frac{1}{4}]{T_1^4} \cong T_A \left( 1 + \frac{6}{4} \left( \frac{v_1}{T_A} \right)^2 + \ldots \right) \]

and neglecting higher ordered terms, and solving for \( T_A \), then
\[ T_A = \sqrt[\frac{1}{4}]{T_1^4 - \frac{3}{2} \left( \frac{v_1}{T_A} \right)^2} \]

If \( (v_1/T_A)^2 \) is small compared to one then
\[ \sqrt[\frac{1}{4}]{T_1^4} \cong T_A^4 \]

and equation (23) simplifies to
\[ (mc)_1 \frac{\partial T_A}{\partial t} = P_1 + SA_{1,s} a_{s,i} + A_i \phi_{a,i} a_{s,i} + A_i \phi_i \sum a_i \]

\[ - A_i \xi_i \eta T_A^4 + \sum_{j=1}^{N} \eta_{j,i} (T_{A_j} - T_A) \]

\[ + \sum_{j=1}^{N} R_{j,i} (T_{A_j}^4 - T_A^4) \]
Spacecraft having some spin about the axis of symmetry usually satisfy equation (25a), while spacecraft having no spin about the axis of symmetry may have strong surface temperature differences. In this case each conical section of the spacecraft's surface must be divided into smaller sections until the condition

\[ T_1^{\frac{4}{3}} \approx T_4^{\frac{4}{3}} \]

is satisfied. For such a situation the required labor may become so great that other methods of solution must be employed.

Techniques will be developed later which will enable one to calculate the magnitude of the circumferential temperature variations.

Example of spacecraft temperature variations. - Explorer XVI is an example of a spacecraft which conforms to the assumptions employed in arriving at equation (26) and can be used as an example to illustrate the use of the system of equations described by equation (26).

For this illustration the Explorer XVI spacecraft is subdivided into 12 sections. An equation for each section is written and all 12 equations are integrated simultaneously for several orbital conditions. For purposes of visual definition, a picture of Explorer XVI is presented as figure 21(a). In figure 21(b) Explorer XVI is shown with each thermal section numbered. The thermal properties for these sections are listed below:

Thermal section 1 (forward solar cells)

\[(mc)_1 = 0.145 \text{ Btu/°R}\]

\[(A)_1 = 32.2 \text{ in.}^2\]
Thermal section 2 (sounding boards)

\[(mc)_2 = 0.217 \text{ Btu/FR} \]

\[(A)_2 = 222 \text{ in.}^2 \]

\[(a_0)_2 = 0.71 \]

\[(\Sigma)_2 = 0.42 \]

Thermal section 3 (side solar cells and ring)

\[(mc)_3 = 1.431 \text{ Btu/FR} \]

\[(A)_3 = 337 \text{ in.}^2 \]

\[(a_0)_3 = 0.71 \]

\[(\Sigma)_3 = 0.72 \]

Thermal section 4 (telemeter housing)

\[(mc)_4 = 1.354 \text{ Btu/FR} \]

\[(A)_4 = 504 \text{ in.}^2 \]

\[(a_0)_4 = 0.71 \]

\[(\Sigma)_4 = 0.42 \]
Thermal section 5 (telemeter modules)

\[(mc)_5 = 0.336 \text{ Btu/°R}\]

Thermal section 6 (telemeter covers)

\[(mc)_6 = 1.262 \text{ Btu/°R}\]

Thermal section 7 (telemeter support structure)

\[(mc)_7 = 1.627 \text{ Btu/°R}\]

Thermal section 8 (inner heat shield)

\[(mc)_8 = 2.00 \text{ Btu/°R}\]

Thermal section 9 (Langley pressure cells)

\[(mc)_9 = 3.30 \text{ Btu/°R}\]

\[(A)_9 = 3016 \text{ in.}^2\]

\[(a_c)_9 = 0.19\]

\[(\varepsilon)_9 = 0.16\]

Thermal section 10 (Lewis sensors)

\[(mc)_{10} = 1.677 \text{ Btu/°R}\]

\[(A)_{10} = 564 \text{ in.}^2\]

\[(a_c)_{10} = 0.32\]

\[(\varepsilon)_{10} = 0.82\]
Thermal section 11 (condenser section)

\( (mc)_{11} = 0.32 \text{ Btu/}^\circ\text{R} \)

\( (A)_{11} = 369 \text{ in.}^2 \)

\( (n_S)_{11} = 0.66 \)

\( (n)_{11} = 0.52 \)

Thermal section 12 (transition section)

\( (mc)_{12} = 0.520 \text{ Btu/}^\circ\text{R} \)

\( (A)_{12} = 360 \text{ in.}^2 \)

\( (n_S)_{12} = 0.23 \)

\( (n)_{12} = 0.76 \)

The radiative heat-transfer coefficients of importance are

\[ R_{9,8} = 9.63 \times 10^{-10} \text{ Btu/min} \cdot ^\circ\text{R}^4 \]

\[ R_{1,4} = 0.06 \times 10^{-10} \text{ Btu/min} \cdot ^\circ\text{R}^4 \]

\[ R_{6,4} = 0.0269 \times 10^{-10} \text{ Btu/min} \cdot ^\circ\text{R}^4 \]

The conductive heat-transfer coefficients of importance are

\[ h_{4,7} = 3.14 \times 10^{-4} \text{ Btu/min} \cdot ^\circ\text{R} \]

\[ h_{4,1} = 0.3276 \text{ Btu/min} \cdot ^\circ\text{R} \]
\[ h_{10,2} = 0.100 \text{ Btu/min} \cdot \theta_T \]
\[ h_{7,0} = 0.3864 \text{ Btu/min} \cdot \theta_T \]
\[ h_{0,2} = 2.542 \text{ Btu/min} \cdot \theta_T \]
\[ h_{8,10} = 0.1536 \text{ Btu/min} \cdot \theta_T \]
\[ h_{10,11} = 0.0187 \text{ Btu/min} \cdot \theta_T \]
\[ h_{11,12} = 0.0187 \text{ Btu/min} \cdot \theta_T \]
\[ h_{7,6} = 6.652 \times 10^{-4} \text{ Btu/min} \cdot \theta_T \]
\[ h_{6,6} = 5.75 \times 10^{-2} \text{ Btu/min} \cdot \theta_T \]
\[ h_{7,6} = 1.36 \times 10^{-3} \text{ Btu/min} \cdot \theta_T \]
\[ h_{7,8} = 0.1536 \text{ Btu/min} \cdot \theta_T \]
\[ h_{10,12} = 0.041 \text{ Btu/min} \cdot \theta_T \]

For design purposes and temperature calculation it has been assumed that the internal power dissipated was 0.4 watt in section 5.

The value of the solar constant used in the calculations was 0.04968 Btu/in.\(^2\) \cdot \text{min}; the albedo \((r_e)\) used was 0.4. The radius of the earth is assumed to be approximately 3441 nautical miles, and the nominal orbit had an assumed perigee of 3715 nautical miles and an apogee of 4189 nautical miles.

The system of equations (given by eq. (26)) was integrated simultaneously for all 12 sections, and for the orbital conditions
producing the highest and lowest telemetered temperature levels. These results are plotted in figures 13(a), 13(b), 13(c), 13(d), 13(e), and 13(f).

It should be noted that in these figures the integration has not been carried out over a time long enough for the telemeters to reach equilibrium values. If the integrations were continued indefinitely, the telemeter temperature would tend to 45°F in the coldest case, and 115°F in the hottest case.

Explorer XVI was successfully launched from Wallops Island Station on December 17, 1962; as of this writing the spacecraft is still transmitting data. The (flight) measured temperature data, for some of the more important sections of Explorer XVI, are plotted on figures 19(a), 19(b), 19(c), 19(d), 19(e), and 19(f); also the maximum and minimum temperatures predicted from figures 13(a), 13(b), 13(c), 13(d), 13(e), and 13(f) are shown (see ref. 8 also).

G. A Parametric Study of Orbital Heating

A parametric study of equation (26) is easily the most powerful tool available to the spacecraft thermal designer.

If some section of a spacecraft is free of thermal coupling with other sections of the vehicle, then its heat balance is greatly simplified and the more fundamental characteristics of equation (26) appear. For example, equation (26) becomes

\[(mc)\frac{dT_A}{dt} = P + 3A_e a_s + A\phi_a c_s + A\phi_e E - A\omega T_A^4.\]  (27)
after setting
\[ R_{j,i} = h_{j,i} = 0 \]
and after dropping the subscript \( i \). From the previous development of \( \phi_0 \) and \( \phi_\alpha \) it is clear that \( \phi_\alpha \) contains a term which is multiplied by
\[ \sin B_\alpha \cos \gamma_0 \]
However, this term is small and its average over \( B_\alpha \) is zero. Too, from figure 14(a) it is evident that
\[ G_\alpha(\Omega_0, \eta_e) \simeq G_\alpha(\Omega_0, \eta_e) \tag{28} \]
This last approximation will be used in this section since \( G_\alpha(\Omega_0, \eta_e) \) is much more amendable to analytical treatment than \( G_\alpha(\Omega_0, \eta_e) \). An approximate, but more enlightening form, of \( \phi_\alpha(\eta_e, \Omega_0) \) can be derived from the following considerations. From equation (9)
\[ \hat{\phi}_e = \frac{A}{\pi} \oint S J_\eta(\eta) \sin \theta d\theta d\gamma \]
where \( \hat{\phi}_e \) signifies that the spacecraft is in the 'long-term spin mode.' Under the assumptions used to derive \( \hat{\imath}(\eta) \) it can be shown that
\[ \hat{\imath}(\eta - \pi/2) \equiv \hat{\imath}(\pi/2 - \eta) \]
and if \( (\eta - \pi/2) \) is replaced by \( \alpha \), then
\[ \hat{\imath}(\alpha) \equiv \hat{\imath}(-\alpha) \tag{29} \]
The calculation of $\eta$ as $\eta(\beta)$ is troublesome and one should be happy in finding an approximation which would circumvent this difficulty. Accounting for equation (29)

$$\int_0^{2\pi} \int_0^{\pi/2} J_e \hat{\eta}(\eta) \sin \theta \, d\gamma = 2 \int_0^{2\pi} \int_0^{\pi/2} J_e \hat{\eta}(\eta) \sin \theta \, d\gamma$$

From the theory of probability, the expectation value of $\hat{\eta}(\eta)$, for a body which is equally likely to have all possible orientations, is defined by

$$\langle \hat{\eta}(\eta) \rangle = \frac{1}{4\pi} \int_0^{2\pi} \int_0^{\pi} \hat{\eta}(\eta) \sin \theta \, d\theta \, d\gamma$$

Now setting

$$\hat{\eta}(\eta) = \left[ \hat{\mu} - \langle \hat{\mu} \rangle \right] + \langle \hat{\mu} \rangle$$

so $\phi_e$ can be expressed as

$$\phi_e = \frac{J_e A}{x} \int_0^{2\pi} \int_0^{\pi/2} \left[ \hat{\mu} - \langle \hat{\mu} \rangle \right] + \langle \hat{\mu} \rangle \sin \theta \, d\theta \, d\gamma$$

or

$$\phi_e = \frac{J_e A}{x} \int_0^{2\pi} \int_0^{\pi/2} \left[ \hat{\mu} - \langle \hat{\mu} \rangle \right] + \langle \hat{\mu} \rangle \sin \theta \, d\theta \, d\gamma$$

or

$$\phi_e = -\frac{J_e A}{x} \int_0^{2\pi} \int_0^{\pi/2} \left[ \hat{\mu} - \langle \hat{\mu} \rangle \right] + \langle \hat{\mu} \rangle \sin \theta \, d\theta \, d\gamma$$
\[ \hat{\phi}_e = 2J_e A(\hat{n})(1 - \cos \theta_0) - \left( \frac{J_e A}{\pi} \right) \int_0^{2\pi} \int_0^\pi \left( \hat{n} - \langle \hat{n} \rangle \right) \sin \theta \, \mathrm{d}\theta \, \mathrm{d}\phi \]

It is easy to show the expectation value of the last integral is zero. After neglecting that last small integral, then

\[ \hat{\phi}_e \approx 2A J_e (1 - \cos \theta_0) \langle \hat{n} \rangle \]

Now a randomly oriented body can be represented by a sphere of equal area \( A \), thus

\[ \langle \hat{n} \rangle = \frac{1}{\sqrt{3}} \]

and

\[ \hat{\phi}_e \approx \left( \frac{A}{2} \right) J_e (1 - \cos \theta_0) \]

(30)

with this amazingly simple approximation and with equation (26), equation (27) now becomes

\[
\begin{align*}
(\mathbf{m})_{\text{eq}} \frac{\mathrm{d}^2 \theta}{\mathrm{d}t^2} &= P + S A_B a_B + \frac{4}{3} S \mathbf{r} e a_B (1 - \cos \theta_0) \cos \theta B_B \\
&+ \frac{4}{3} (\omega T e - i) (1 - \cos \theta_0) - A \omega T A - i \end{align*}
\]

(31)

It should be noted here that the foregoing development is possible if and only if \( \hat{\theta}(\alpha) = \hat{\theta}(-\alpha) \); otherwise the spacecraft's motion must be completely random.

An upper bound on the error incurred may be found by replacing \( [\hat{n} - \langle \hat{n} \rangle] \) with
\[ (\hat{\mu} - \langle \hat{\mu} \rangle)_{\text{max}} = \tilde{\nu} \]

in the integral just neglected. In this case

\[
\text{Error in } \hat{\phi}_e \leq \left| \left(\frac{\frac{\Delta A}{\pi}}{\pi} \right) \frac{2\pi}{\nu} \sin \theta_0 \right| = 2W_2 \frac{A}{\nu} \cos \theta_0
\]

It is interesting to note that the neglected integral is zero for \( \theta_0 = 0 \) or for \( \theta_0 = \frac{\pi}{2} \); that is, equation (30) is exact for either very high or very low altitudes.

The calculation of \( \hat{\phi}_e \) by this technique requires no prior knowledge of the orientation of the spacecraft.

In equation (31) if the member in question is a thin shell of uniform thickness

\[ m = \tau \rho \]

where \( \tau \) is shell thickness and \( \rho \) is the density of the shell, then equation (31) becomes, after division by \( A \) and the substitution of equation (21),

\[
\tau \rho c \frac{dT_A}{dt} = \left( \frac{P}{A} \right) + \frac{S}{A} a_S + S e a_e \left( \frac{1 - \cos \theta_0}{2} \right) \cos \epsilon \cos^*(5 - \varsigma)
+ \left( \frac{T_a}{4} \right) \frac{1 - \cos \theta_0}{2} - \epsilon \tau T_a^4
\]

\[ (32) \]
For a slightly eccentric orbit, the effects of eccentricity on heating rates (of the albedo and earth thermal energy incident on the spacecraft) are of the same order of magnitude as the error introduced into equation (32) by employing equation (30). For this reason, the effects of orbit eccentricity will be neglected in this development. Setting the right-hand side of equation (32) equal to \( q(t) \) then

\[
\tau \rho c \frac{dT_A}{dt} + \mathcal{E} \sigma T_A^4 = q(t)
\]

where

\[
q(t) = q(t + L)
\]

A basic understanding of orbital heating can be obtained from equation (33). Notice that

\[
\int_t^{t+L} \tau \rho c \left( \frac{dT_A}{dt} \right) dt = (\tau \rho c) \int_t^{t+L} dT_A = (\tau \rho c) \left[ T_A(t + L) - T_A(t) \right]
\]

then since \( T_A \) is periodic on \( L \), this integral vanishes. Now set

\[
\frac{1}{L} \int_t^{t+L} \mathcal{E} \sigma T_A^4 dt = \mathcal{E} \sigma T_0^4 = \text{constant}
\]

so that

\[
T_A^4 = \frac{1}{L \mathcal{E} \sigma} \int_t^{t+L} q(t) dt
\]
or, when the indicated integration has been performed,

\[
T_{\theta_0}^4 = \left( \frac{P}{\Sigma \sigma} \right) + \left( \frac{a_0}{L} \right) \left( \frac{L_1}{L} \right) \left( \frac{A_0}{A} \right) + \frac{r_e \cos \epsilon (1 - \cos \theta_0)}{2\pi} \right) \\
+ \left( \frac{T_{\theta_0}}{2} \right) (1 - \cos \theta_0)
\]

(34)

Here \( T_{\theta_0}^4 \), the mean equilibrium temperature raised to the fourth power, represents the fourth power temperature level which the temperature of the surface in question is attempting to attain.

Some of the more important aspects of orbital heating, as received by a spacecraft, becomes obvious in equation (34). To more clearly illustrate the effects of these contributions consider a spacecraft with the following properties:

\[
\left( \frac{a_0}{L} \right) = 1.2
\]

\[
\left( \frac{L_1}{L} \right) = 0.65
\]

\[
\left( \frac{A_0}{A} \right) = \frac{1}{4}
\]

\( \theta_0 = 60^\circ \); altitude = 550 nautical miles

\( P = 0 \)

\( L_1 = \) time in sunlight
These numbers are representative of a near-earth spacecraft in a circular orbit. For this configuration

\[ T_{\lambda_0}^4 \simeq \left[ 484 \times 10^6 \right] + \left[ 99 \times 10^6 \right] \cos \epsilon + \left[ 103 \times 10^6 \right] \]

The first term in brackets is the direct solar heating term; the second term in brackets is the albedo contribution; and the last term in brackets is the earth-thermal energy input. For this configuration the largest value of \( T_{\lambda_0}^4 \) is

\[ T_{\lambda_0}^4 = 692 \times 10^6 \text{, or } T_{\lambda_0} \simeq 53^0 F \]

while the least value is

\[ T_{\lambda_0}^4 = 587 \times 10^6 \text{ or } T_{\lambda_0} \simeq 32^0 F \]

The temperature variation is due to the coefficient of \( \cos \epsilon \).

It has been demonstrated by this example that the earth's thermal and albedo heating alters the spacecraft's temperature; however, the individual contributions are small.

From equation (34) it is clear that the ratio

\[ \left( \frac{a_2}{\lambda} \right) \]

is a design variable important to the determination of the direct solar heating. Also, the albedo heating is a linear function of \( \left( \frac{a_2}{\lambda} \right) \) and \( \cos \epsilon \). Perhaps the most surprising effect is that the contribution from earth thermal heating is dependent solely on \( \cos \beta_0 \). One should keep in mind the conditions for which equation (34) is valid.
One final word before proceeding to the next problem. The conditions used to derive equation (27) from equation (26) need not always exist since the effects of conduction cannot be propagated over long distances in thin shells when radiation is admitted to the shell's surfaces. These bodies tend toward thermal equilibrium when their radiation environment is at a large distance from those locations where conductive heating is effective. For example, if two long cylinders, with drastically different optical properties, are joined with conductive heat paths, equation (27) is still valid at some distance away from the conducting joint.

H. Solution for the Nonlinear Heat Equation

Before an actual solution of equation (33) can be effected, one must realize that equation (33) is nonlinear and has no known exact solution. Too, the nonlinear term is not small and hence is not amendable to the normal perturbation technique, for nonlinear equations, such as that given in reference 4.

Suppose, however, an approximate solution \( T_{\Lambda 0} \) to equation (27) is known. When \( T_{\Lambda 0} \) is introduced it follows that

\[
\frac{d}{dt} T_{\Lambda 0} + E_0 T_{\Lambda 0} = q(t) + \tilde{r}_1(t) \tag{35}
\]

where \( \tilde{r}(t) \) (the modified \( q(t) \)) measures the error in using \( T_{\Lambda} = T_{\Lambda 0} \), and \( T_{\Lambda 0} \), in this case, is a function of time. Also, \( T_{\Lambda} \) could be written as

\[
T_{\Lambda} = (T_{\Lambda 0} + v_0); \quad v_0 \ll T_{\Lambda 0}
\]
hence

\[ T'_{\Lambda} = T_{\Lambda} + 4T_{\Lambda}^3v_0 + 6T_{\Lambda}^2v_0^2 + 4T_{\Lambda}v_0^3 + v_0^4 \]  
(36)

When equations (35) and (36) are combined with equation (33), the result is found to be

\[ \tau \rho c \left[ \frac{dT_{\Lambda}}{dt} + \frac{\dot{v}_0}{dt} \right] + \Sigma \left[ T_{\Lambda} - 4T_{\Lambda}^3v_0 + 6T_{\Lambda}^2v_0^2 + 4T_{\Lambda}v_0^3 + v_0^4 \right] \]

\[ = q(t) = \rho c \frac{dT_{\Lambda}}{dt} + \Sigma T_{\Lambda} = \tilde{r}_1(t) \]

which simplifies to

\[ \tau \rho c \left[ \frac{\dot{v}_0}{dt} \right] + \Sigma \left[ 4T_{\Lambda}^3v_0 + 6T_{\Lambda}^2v_0^2 + 4T_{\Lambda}v_0^3 + v_0^4 \right] = -\tilde{r}_1(t) \]  
(37)

where

\[ \tilde{r}_1(t) \approx 6T_{\Lambda}^2v_0^2 \approx 4T_{\Lambda}v_0^3 \approx v_0^4 \]

Now setting

\[ \tilde{r}_1(t) = r_1(t) + \tilde{r}_2(t) \]

\[ v_0 = \Lambda_{1} + v_t; \quad \Lambda_{1} \gg v_t \]

then if this symbolism is substituted into equation (37), and the smaller nonlinear terms are separated into an equation for \( v_t \), the result is given by
\[ \frac{\partial \Lambda_\alpha}{\partial t} + \Sigma_{0} \left[ 4T_{0} \Lambda_\alpha \right] = -i_{1}(t) \] (38)

and the separated part is

\[ \frac{\partial v_{1}}{\partial t} + \Sigma_{0} 4T_{0} \Lambda_\alpha + \Sigma_{0} T_{0}^{2}(\Lambda_{1}^{2} + \Sigma_{1} v_{1} + v_{1}^{2}) \]

+ (smaller nonlinear terms) = \( -i_2(t) \) (39)

Next writing

\[ v_{1} = \Lambda_{2} + v_{2}; \Lambda_{2} \gg v_{2} \]

\[ i_{2} = i_{2}(t) + i_{3}(t) \]

this assumption may be substituted into equation (39) and, upon retention of larger terms only,

\[ \frac{\partial \Lambda_\alpha}{\partial t} + \Sigma_{0} \left[ 4T_{0} \Lambda_{2} + \Sigma_{0} T_{0}^{2} \Lambda_{1}^{2} \right] = -i_{2}(t) \] (40)

This process can be continued ad infinitum, thus for every \( \Gamma_{n}(t) \) there is a corresponding \( \Lambda_{n} \) where

\[ \Lambda_{n} = \Lambda_{n}(t, \xi_{n}, \Lambda_{n-1}, \Lambda_{n-2}, \ldots, \Lambda_{0}) \]
Since the choice of $\Gamma_n$ is arbitrary it will be assumed that $\Gamma_n$ can be chosen such that

$$T_{\Lambda n} \ll T_{\Lambda n-1}$$

or, more specifically,

$$T_{\Lambda n} = O\left(\Delta T_{\Lambda n-1}\right)$$

where $\Delta \ll 1$ and is fixed by one's choice of $\Gamma_n(t)$.

Experience has shown that for equations of the type given in this thesis, the proper choice of $\Gamma_n$ is

$$\Gamma_2(t) = \Gamma_3(t) = \Gamma_4(t) = \ldots = 0$$

if $\tilde{r}_1(t)$ is selected by equation (35), and if $T_{\Lambda 0}$ is a 'near solution' to $T_{\Lambda}$. Thus a solution is obtained as

$$T_{\Lambda} = T_{\Lambda 0} + T_{\Lambda 1} + T_{\Lambda 2} + \ldots$$

where

$$T_{\Lambda n} = O\left(\Delta^n T_{\Lambda 0}\right); \quad \tilde{r}_1 = \sum_{n=1}^{\infty} \Gamma_n(t) = \text{modified forcing function}$$

The development of a solution for equation (33) has, to this point, been an intuitive argument intended to persuade the reader that such a solution method exists. Actually, there is a much easier method of arriving at the same solution.
The first step in achieving the solution is to assume that the solution exists in the form

\[ T_\Lambda = T_{\Lambda 0} + T_{\Lambda 1} + T_{\Lambda 2} + T_{\Lambda 3} + \ldots \]

where \( T_{\Lambda 0} \) is an approximate solution and

\[
0 \left\{ \begin{array}{c} T_{\Lambda k} \\ T_{\Lambda j} \end{array} \right\} = 0 \left\{ T_{\Lambda k+j} \right\}
\]

\[
0 \left\{ T_{\Lambda n} \right\} = 0 \left\{ \Delta T_{\Lambda n-1} \right\}, \Delta < 1
\]

If the differential equation has a forcing function, its modified forcing function must be rewritten as

\[ \tilde{\Gamma}_1 = \Gamma_1 + \Gamma_2 + \Gamma_3 + \ldots \]

where

\[
0 \left\{ \tilde{\Gamma}_n \right\} = 0 \left\{ T_{\Lambda n} \right\}
\]

and

\[ \tilde{\Gamma}_n = \Gamma_n + \tilde{\Gamma}_{n+1} \]

In every case \( \tilde{\Gamma}_{n+1} \) is that portion of \( \tilde{\Gamma}_n \) which would cause \( T_{\Lambda n} \) to diverge, and \( \tilde{\Gamma}_1 \) is determined by equation (35).

The second step (in finding the solution to eq. (33)) is to substitute the assumed solution form into equation (33) and require that the resulting expression be satisfied at each order of magnitude level.
The third step is to solve the resulting system of linear differential equations with their appropriate boundary conditions.

Hereafter, in this thesis, a direct approach will be used; namely, to find solutions for the nonlinear differential equations which will be encountered in connection with thermal design.

I. Solution of the Heat Equation for Spacecraft

Having Uniform Temperatures

The solution of equation (35) can be found by the method related in the previous section.

Assume the solution to be of the form

$$T_A = T_{A_0} + T_{A_1} + T_{A_2} + T_{A_3} + \ldots$$

so that

$$T_A^{\hat{4}} = (T_{A_0}^{4}) + (4T_{A_0}^{3}T_{A_1}) + (4T_{A_0}^{2}T_{A_2} + 6T_{A_0}T_{A_1}^{2}) + \ldots$$

and

$$\frac{dT_A}{dt} = \left(\frac{dT_{A_0}}{dt}\right) + \left(\frac{dT_{A_1}}{dt}\right) + \left(\frac{dT_{A_2}}{dt}\right) + \ldots$$

then, when this is substituted into equation (35) it is found that

$$\tau_{dc} \left\{ \left(\frac{dT_{A_0}}{dt}\right) + \left(\frac{dT_{A_1}}{dt}\right) + \left(\frac{dT_{A_2}}{dt}\right) + \ldots \right\} + (\Sigma G) \left\{ (T_{A_0}^{4}) + (4T_{A_0}^{3}T_{A_1}) + (4T_{A_0}^{2}T_{A_2} + 6T_{A_0}T_{A_1}^{2}) + \ldots \right\} = q(t) = \frac{1}{L} \int_{t}^{t+L} q(t) \, dt + \int_{t}^{t+L} \left\{ q - \frac{1}{L} \int_{t}^{t+L} q(t) \, dt \right\} dt$$

$$= (41)$$
From a previous development it is evident that

\[ q(t) = q(t + L) \]

and from the previous development, it is also obvious that within certain bounds \( T_{\lambda_0} \) is arbitrary. It is also evident from equation (39) that the most practical choice of \( T_{\lambda_0} \) is

\[ T_{\lambda_0} = \text{constant}, \quad \frac{dT_{\lambda_0}}{dt} = 0 \quad (42) \]

so that

\[ 2\sigma T_{\lambda_0}^h = \frac{1}{L} \int_t^{t+L} q(t) dt \quad (43) \]

Requiring that the remaining terms be satisfied on apparent order of magnitude levels, the following system of linear differential equations is obtained

\[ \tau_0 e \frac{dT_{\lambda_1}}{dt} + \Sigma e^{\delta_i T_{\lambda_0}} \frac{dT_{\lambda_1}}{dt} = q - \frac{1}{L} \int_t^{t+L} q(t) dt = \bar{F}_1(t) \]

\[ \tau_0 e \frac{dT_{\lambda_2}}{dt} + \Sigma e^{\delta_i T_{\lambda_0}} \frac{dT_{\lambda_2}}{dt} = -\Sigma e^{\delta_i T_{\lambda_0}} T_{\lambda_1}^2 \]

\[ \tau_0 e \frac{dT_{\lambda_3}}{dt} + \Sigma e^{\delta_i T_{\lambda_0}} \frac{dT_{\lambda_3}}{dt} = -\Sigma \{ \ldots \} \]

and so forth.
The solution of equation (43) is given by equation (34).

Now, writing

\[ q(t) = \Sigma cT_{eq}^{L} \]

the differential equation for \( T_{A1} \) can be rewritten as

\[
(\tau c) \frac{dT_{A1}}{dt} + (\Sigma cT_{A0}^{L})T_{A1} = (\Sigma c) \left[ T_{eq}^{L} - T_{A0}^{L} \right] = \Sigma cT_{A0}^{L} \left[ T_{Aeq} - T_{A0}^{L} \right] - 1
\]

\[ (44) \]

(It is often convenient to work with the non-dimensionalized temperature \( \xi_n \) which is equal to \( T_{A1}/T_{A0} \)), after rewriting, the equation for \( T_{A1} \) becomes

\[
(\tau c)T_{A0} \frac{d\xi_{1}}{dt} + h(\Sigma cT_{A0}^{L})\xi_{1} = (\Sigma cT_{A0}^{L}) \left[ \xi_{eq}^{L} - 1 \right]
\]

\[ (45) \]

Now setting

\[
\tau cT_{A0} = \bar{c}, \quad \Sigma cT_{A0}^{L} = \bar{q}, \quad \frac{\bar{q}}{c} = \frac{\lambda}{h}
\]

the well-known solution of equation (45) is, from reference 5,

\[
\xi_{1} = \left( \frac{\lambda}{h} \right) \exp \left( -\lambda_{T} t \right) \int_{0}^{t} \exp \left( \lambda_{T} t_{1} \right) \left[ \xi_{eq}^{L} - 1 \right] dt_{1} + c_{1} \exp \left( -\lambda_{T} t \right)
\]

The only condition placed on this result is that \( \xi_{1}(t) = \xi_{1}(t + L) \), or
\[ c_1 \left[ 1 - \exp(-\lambda T L) \right] = \frac{\lambda T}{4} \exp(-\lambda T L) \int_0^L \exp(\lambda_T t_1) \left[ \xi_{eq}^4 - 1 \right] dt_1 \]

so that

\[ \xi_1 = \frac{\lambda T}{4} \exp(-\lambda T t) \int_0^t \exp(\lambda_T t_1) \left[ \xi_{eq}^4 - 1 \right] dt_1 \]

\[ + \frac{\exp(-\lambda T L)}{1 - \exp(-\lambda T L)} \int_0^L \exp(\lambda_T t_1) \left[ \xi_{eq}^4 - 1 \right] dt_1 \]

(46)

where \( t_1 \) is a dummy variable.

The differential equation for \( T_{\Lambda} \) may be rewritten as

\[ (\nu \rho c T_{\Lambda}) \frac{d\xi_2}{dt} + 4(\frac{\xi_{eq}^4}{T_{\Lambda}^2}) \xi_2 = -6(\frac{\xi_{eq}^4}{T_{\Lambda}^2}) \xi_1^2 \]

Its solution is

\[ \xi_2 = -\frac{3}{2} \lambda_T \exp(-\lambda T t) \int_0^t \exp(\lambda_T t_1) \left[ \xi_{eq}^2 \right] dt_1 \]

\[ + \frac{\exp(-\lambda T L)}{1 - \exp(-\lambda T L)} \int_0^L \exp(\lambda_T t_1) \left[ \xi_{eq}^2 \right] dt_1 \]

(47)

An oddity of \( T_\Lambda(t) \) can be shown as follows: the average value of the forcing function (right-hand side of eq. (45)) is zero, hence the mean value of \( \xi_1 \) is zero. However, \( \xi_1^2 \) can be written as
\[ z_2 = \frac{1}{L} \int_0^L z_1^2 \, dt_1 + \left\{ z_2 - \frac{1}{L} \int_0^L z_1^2 \, dt_1 \right\} \]

\[ = (z_2)_{m} + (z_2)_{var} \]

where the mean value of \((z_1^2)_{m}\) is zero. Thus \(z_2\) is composed of var (like all functions) of a mean valued term plus a term which fluctuates about the mean value. Now introducing only the mean value of \(z_1^2\) into equation (47), one obtains

\[ (z_2)_{m} = -\frac{3}{2}(z_1^2)_{m} \quad (48) \]

Thus the mean value of \(T_0\) can be approximated by

\[ (T_0)_{m} = T_0 \left(1 - \frac{3}{2}(z_1^2)_{m}\right) = T_0 - \frac{3}{2} \frac{(T_1^2)_{m}}{T_0} \quad (49) \]

(Notice the close similarity to eq. (25).) The importance of \((\lambda t/4)\), the ratio of the mean radiant heat rate to the mean heat content, is illustrated by equations (44) through (48). In equation (46), as \(t\) becomes very large the constant term becomes negligible so that

\[ z_1 = \frac{\lambda t}{4} \exp(-\lambda t) \int_0^t \left[ z_{eq} - 1 \right] \exp(\lambda t) \, dt_1 \]

and as \(\lambda t \to 0\); \(z_1 \to 0\) and a large \(\lambda t\) implies a large \(z_1\).
For a given mean heat rate per orbital pass, and for $\lambda_T$ equal to zero, there is a corresponding mean temperature $T_{\Delta 0}$ (as calculated by eq. (34)). As $\lambda_T$ grows to some finite value, $\xi_1$ also grows to some finite value; this implies that $(\xi_1^2)_m$ increases and that $T_{\Delta 0}$ decreases in agreement with equation (46). It is obvious that the same argument holds for a discussion of the effects of the size of

$$\left[ \xi_{eq} - 1 \right]$$

It will be demonstrated later how these two facts are of vital importance in the passive thermal design of a spacecraft.

Next, notice that the largest term in the temporal temperature variations is given by equation (46). For a given $\xi_{eq}(t)$, the parameter in equation (46) which distinguishes between various spacecrafts, is the parameter $(\lambda_T)$. An inspection of equation (47) shows that the correction, which contains the nonlinear properties of the temporal temperature fluctuation, is also defined by $(\lambda_T)$. Thus the temporal temperature fluctuations are a function of $(\lambda_T)$ for a given $\xi_{eq}^{\frac{1}{4}}$. This property could also be derived from the governing differential equation.

It should be recalled that $\xi_{eq}^{\frac{1}{4}}$ is the ratio of surface averaged heat rate incident on the spacecraft to the surface and time averaged heat rate incident on the spacecraft. The parameter $(\lambda_T)$ is one-fourth of the ratio of the time and space averaged heat rate incident on the spacecraft to the mean heat stored in that surface. The factor of one quarter has no special significance for this particular interpretation of $(\lambda_T)$. 
Inspection of equation (46) shows that the temperature approaches its periodic value, exponentially as a first approximation.

The technique of solution used in this thesis is nothing more than the well-known method of successive approximations employed so as to resemble a perturbation technique. No attempt at a convergence proof is given since it is doubtful that one exists. Instead, it will be shown, by numerical examples, that this method does yield acceptable results for this type of problem.

It is obvious that through terms like $T_{A0} + T_{A1}$ the method of solution used here reduces to the often used linearization method where $T_{A0}$ plays the role of a constant. For an example of the linearization scheme see references 6 and 7.

No numerical example is given in this section since it is, in reality, a special case of the following section.

J. Solution of the Heat Equation for a Cylindrical Spacecraft With Time Dependent Temperature Distributions

When strong circumferential temperature differences are present on a spacecraft's external surfaces, the solution of the system of differential equations (described by eq. (25)) may be excessively involved. An alternate method for calculating the surface temperature distributions can be found in the solution of

$$\nabla \cdot \tilde{q}_T + \frac{q_n}{\tau} + P \approx \rho c \frac{\partial T}{\partial t}$$  \hspace{1cm} (3)

In general, $P$ is zero unless electric currents flow in the member; thus $P$ is of no interest here. The term $q_n$ is the radiant heat
flux (arriving and leaving) the vehicular shell surface. The \( q_r \) term is the heat transferred, in the vehicle's tangent plane, by conduction.

It would be impractical to solve equation (3) for a general cone and then try to join cones together in a manner so as to find the temperature distribution for an arbitrary body of revolution. A situation, more amenable to solution, is that of a cylindrical shell with insulated ends and inner walls.

The solution for this example is straightforward and the results can be used to define bounds, or temperature limits, for the more difficult shapes.

As the 'example cylinder' orbits the earth its surface continually sees changing heat rates. Some surfaces receive more heat than others, thus the temperature along the cylinder's circumference is not uniform. Cylindrical polar coordinates are the natural coordinate system for this problem.

In cylindrical polar coordinates (see fig. 10) let the principal axis be aligned with the \( z_0 \) axis. Then, the cylinder's tangent plane is perpendicular to \((\hat{e}_r)\). If the cylinder in question has no thermal coupling to other bodies, and if its optical properties are uniform, then there is no heat flow in the \( z \) direction; hence equation (3) simplifies to

\[
\frac{K}{r^2} \frac{\partial^2 T}{\partial \theta^2} + \frac{q_n}{r} \approx \rho C \frac{\partial T}{\partial t} \tag{50}
\]
where

- $r$ is the radius of the cylinder
- $K$ is the thermal conductivity of the surface material
- $t$ is the thickness of the cylinder's walls

The problem of interest here occurs when the spin vector is at right angles to its axis of symmetry (the principal axis). In figure 11

- $(\hat{P}A)$ is the principal axis vector
- $(\hat{S}UN)$ is a vector pointing toward the sun
- $(\tilde{e})$ is the vector pointing toward the earth

- $\gamma_1$ is the angle between the planes $(\hat{n}, \tilde{n})$ and $(\tilde{e}, \tilde{k})$
- $\gamma_2$ is the angle measured from plane $(\hat{n}, \tilde{n})$ to plane $(\hat{\omega}, \hat{S}UN)$

From the law of cosines, in spherical trigonometry

\[
\left\{ \hat{n} \cdot (\hat{S}UN) \right\}^* = \left\{ \cos \Lambda \cos \eta_1 + \sin \Lambda \sin \eta_1 \cos \gamma_2 \right\}^* \quad (51)
\]

\[
\hat{n} \cdot \tilde{e} = \cos \Lambda \cos \eta_e \cos \gamma_1 + \sin \Lambda \sin \eta_e \cos \gamma_2 \quad (52)
\]

and it is clear that

\[
\dot{\gamma}_2 = -\dot{\gamma}_1 = \text{spin rate} = \omega
\]

In this section it will be assumed that the spin is fast enough so that no sizeable temperature fluctuations occur over one spin cycle of $(\hat{P}A)$ about $\hat{\omega}$. If this condition is met (a means of checking
this condition is given in ref. 6), then the heat rates can be averaged over one spin cycle and the rewards of the ensuing simplicity can be achieved.

The solar contribution \( q_s \) to \( q_n \) is calculated as follows:

Setting

\[
\vec{n} \cdot (\vec{\text{SUN}}) = \cos \, \iota_1
\]

\[
\vec{n} \cdot \vec{e} = \cos \, \iota_2
\]

and writing the fourier series

\[
\cos \, \iota_1^* = \sum_{n=0}^{\infty} a_n \cos \, n \iota_1
\]

then with the aid of this expansion and trigonometric identities, along with equation (51), \( \cos \, \iota_1^* \) can be averaged over one revolution of \( \gamma_2 \) to yield

\[
\frac{1}{2\pi} \int_0^{2\pi} \cos \, \iota_1^* d\gamma_1 = \bar{\mu}_0 + \bar{\mu}_1 \cos \Lambda + \bar{\mu}_2 \cos 2\Lambda + \bar{\mu}_4 \cos 4\Lambda
\]

where

\[
\bar{\mu}_0 = a_0 - \frac{a_2}{2} \sin^2 \iota_S + a_4 \left[ 3 \cos \iota_S + 3 \cos^2 \iota_S \sin^2 \iota_S + \frac{3}{2} \sin^4 \iota_S - 2 \cos^2 \iota_S - 1 \right]
\]
\[ \tilde{M}_2 = \frac{a_2}{2} \left[ 2 \cos^2 \eta - \sin^2 \eta \right] + a_4 \left[ 4 \cos \eta - \frac{3}{2} \sin^4 \eta - 4 \cos^2 \eta \right] \]
\[ + 2 \sin^2 \eta \]
or

\[ G_3(\theta_0, \varphi_2) = b_0 + b_1 \cos \varphi_2 + b_2 \cos^2 \varphi_2 \]

where

\[ b_0 = c_0 \left\{ \frac{1}{2} (1 - \cos \theta_0) \right\} + c_2 \left\{ \frac{1}{2} (2 - \cos \theta_0 \sin^2 \theta_0 - 2 \cos \theta_0) \right\} \]

\[ b_1 = c_1 \sin^2 \theta_0 \]

\[ b_2 = c_2 \left\{ \frac{2}{3} (1 - \cos^3 \theta_0) - \frac{1}{2} (2 - \cos \theta_0 \sin^2 \theta_0 - 2 \cos \theta_0) \right\} \]

after applying equation (52) and integrating \( G_3 \) over one cycle of \( \gamma_2 \) and introducing equation (19) it is found that

\[ \frac{2\pi}{c_1^{\frac{1}{2}}} \int_0^{2\pi} G_3(\theta_0, \varphi_2) d\gamma \equiv (G_3(\theta_0, \varphi_2))_{c_1} \equiv \{ n_{01} - n_{02} \cos 2(\delta + \varphi) \}
\]

\[ = \left( n_{11} \sin(\delta + \varphi) \right) \cos \Lambda + n_{21} \]

\[ + n_{22} \cos 2(\delta + \varphi) \cos 2\Lambda \]

(55)

where

\[ n_{01} = \left( b_0 + \frac{b_2}{4} + \frac{b_2}{6} \cos^2 \varphi \right) \]

\[ n_{02} = \left( b_2 \cos^2 \varphi \right) \]
\[ n_{11} = (b_1 \cos \varphi) \]

\[ n_{21} = \left( \frac{3b_2}{8} \cos^2 \varphi - \frac{b_2}{4} \right) \]

\[ n_{22} = \left( \frac{3b_2}{8} \cos^2 \varphi \right) \]

Now applying equation (26), then the earth thermal radiation and the reflected solar radiation can be expressed by

\[ q_e + q_a + q_c = \left( J_e \Sigma + 3r_e a_e \cos \epsilon \cos^* (\delta - \zeta) \right) [g_3(\theta_0, \gamma_0)]_m \]

(56)

The total incoming power (by radiation) is

\[ q_e + q_a + q_c \approx sa_5(\cos \gamma_0^*) m + \left( J_e \Sigma \right. \]

\[ \left. + 3r_e a_e \cos \epsilon \cos^* (\delta - \zeta) \right) [g_5(\theta_0, \gamma_0)]_m \]

This expression can be rearranged and replaced by

\[ q_e + q_a + q_c = f_0(\delta) + f_1(3) \cos \Lambda + f_2(3) \cos 2\Lambda + f_4(3) \cos 4\Lambda \]

(57)

where

\[ f_0(\delta) = \left( sa_5 \right) \bar{w}_0 + \left( J_e \Sigma + 3r_e a_e \cos \epsilon \cos^*(\delta - \zeta) \right) \left( n_0 \right. \]

\[ \left. - n_0 e \cos 2(\delta + \psi) \right) \]
\( f_1(\delta) = \left( \Omega_a \right) \bar{M}_1 - \left( J_e \right) \bar{L} + \Omega e \ a_e \ \cos e \ \cos^2(\delta - \zeta) \ \{ n_{11} \ \sin(\delta + \theta) \} \)

\( f_2(\delta) = \left( \Omega_a \right) \bar{M}_2 + \left( J_e \right) \bar{L} + \Omega e \ a_e \ \cos e \ \cos^2(\delta - \zeta) \ \{ n_{21} - n_{22} \ \cos 2(\delta + \theta) \} \)

\( f_4(\delta) = \left( \Omega_a \right) \bar{M}_4 \)

The heat lost from the spacecraft's external surface by radiation is

\[ \Sigma \sigma T^4 \]

and the net heat on a surface element is, then,

\[ q_n = q_s + q_a + q_2 - \Sigma \sigma T^4 \]

with these results, after multiplication by \( \tau \), equation (50) becomes

\[ \frac{-K_T \ \delta T}{r^2} + \Sigma \sigma T^4 \ + \ \tau \ \rho c \ \frac{\partial T}{\partial t} = f_0(\delta) + f_1(\delta) \cos \Lambda + f_2(\delta) \cos 2\Lambda + f_4(\delta) \cos 4\Lambda \]

Only a few changes are necessary to prepare equation (59) for its solution. First evaluate
\[ \left( \frac{1}{2\pi} \right)^2 \int_0^{2\pi} \rho \, d\rho \int_0^{2\pi} \rho_0 \, d\rho_0 = \frac{1}{2\pi} \int_0^{2\pi} f_0(\delta) d\delta = (f_0)_m \]

then set

\[ T = T \rho_0 \left\{ 1 + \partial_1 + \partial_2 + \ldots \right\} \]

\[ \sum T \rho_0 = \hat{q}_R \]

\[ \tau \rho c T \rho_0 = \hat{a} \]

and

\[ \frac{K T \rho_0}{r^2} = \hat{a}_K \]

so that equation (59) becomes

\[ -\hat{a}_K \left\{ \frac{\partial^2 \partial_1}{\partial \rho^2} + \frac{\partial^2 \partial_2}{\partial \rho^2} + \ldots \right\} \]

\[ + \hat{q}_R \left\{ 1 + 4\partial_1 + 4\partial_2 + 6\partial_1^2 + \ldots \right\} \]

\[ + \hat{q} \left\{ \frac{\partial \partial_1}{\partial t} + \frac{\partial \partial_2}{\partial t} + \ldots \right\} \]

\[ = (f_0)_m + \left\{ f_0(\delta) - (f_0)_m \right\} + f_1(\delta) \cos \Lambda \]
The homogeneous solution (for \( t_1 \)) is of no interest since it is not periodic. The particular solution of \( t_1 \) can be found by assuming

\[
\hat{t}_1 = \hat{e}_0(t) + \hat{e}_1(t)\cos \Lambda + \hat{e}_2(t)\cos 2\Lambda + \hat{e}_4(t)\cos 4\Lambda
\]

When this expression is introduced into equation (61) then, after grouping on \( \cos n\Lambda \), one obtains

\[
\frac{\partial \hat{e}_0}{\partial t} + \lambda T \hat{e}_0 = \frac{1}{Q} \left( \hat{e}_0(t) - (\hat{e}_0)_m \right)
\]

\[
\frac{\partial \hat{e}_1}{\partial t} + (\lambda T + \lambda M) \hat{e}_1 = \frac{1}{Q} \hat{f}_1(t)
\]
\[
\frac{\partial e_2}{\partial t} + (\lambda_T + \lambda_{T2})e_2 = \frac{1}{C} f_2(t)
\]

end

\[
\frac{\partial e_4}{\partial t} + (\lambda_T + \lambda_{T4})e_4 = \frac{1}{C} f_4(t)
\]

where

\[
\lambda_{T1} = \frac{\dot{Q}_K}{Q}; \quad \lambda_{T2} = \frac{\lambda_{T} \dot{Q}_K}{C}; \quad \lambda_{T4} = \frac{16\dot{Q}_K}{C}
\]

Now, set \( \lambda_T + \lambda_{Tn} = \lambda_{Tn} \) then the straightforward solution for this set of linear first-order differential equations is

\[
e_0(t) = \frac{1}{C} \exp(-\lambda_T t) \int_0^t \left( f_0(\delta_1) - (f_0)_m \right) \exp(\lambda_T t_1) dt_1
\]

\[
+ \frac{1}{Q} \exp(-\lambda_T t) \frac{\exp(-\lambda_T L)}{1 - \exp(-\lambda_T L)} \int_0^L \left( f_0(\delta_1) - (f_0)_m \right) \exp(\lambda_T t_1) dt_1
\]

and

\[
e_n(t) = \frac{1}{C} \exp(-\lambda_{Tn} t) \int_0^t f_n(\delta_1) \exp(\lambda_{Tn} t_1) dt_1
\]

\[
+ \frac{1}{Q} \exp(-\lambda_{Tn} t) \frac{\exp(-\lambda_{Tn} L)}{1 - \exp(-\lambda_{Tn} L)} \int_0^L f_n(\delta_1) \exp(\lambda_{Tn} t_1) dt_1
\]
where \( g_n(t) = g_n(t + 1); n > 0 \). When equation (62) is divided by \( \omega \), and with

\[
\frac{\partial K}{\partial \xi} = \lambda \xi; \quad \left( \frac{\partial R}{\partial \xi} \right) = -\frac{\lambda}{4}
\]

introduced, then it follows that

\[
\frac{\partial \xi_2}{\partial t} + \lambda \xi_2 - \lambda \frac{\partial \xi_2}{\partial \Lambda} = -\frac{3}{2} \lambda \xi_1^2.
\]

When \( \xi_1 \) is squared, and terms through \( \cos 4\Lambda \) are retained,

\[
\xi_1^2 = \bar{a}_0 + \bar{a}_1 \cos \Lambda + \bar{a}_2 \cos 2\Lambda + \bar{a}_3 \cos 3\Lambda + \bar{a}_4 \cos 4\Lambda \quad (63)
\]

where

\[
\bar{a}_0 = \left[ \frac{e_0^2}{2} + \frac{e_1^2}{2} + \frac{e_2^2}{2} + \frac{e_4^2}{2} \right]
\]

\[
\bar{a}_1 = \left[ 2e_0 e_1 + e_2 e_2 \right]; \quad \bar{a}_2 = \left[ \frac{e_1^2}{2} + 2e_0 e_2 + e_2 e_4 \right]
\]

\[
\bar{a}_3 = \left[ e_1 e_2 + e_1 e_4 \right]; \quad \bar{a}_4 = \left[ \frac{e_2^2}{2} + 2e_0 e_4 \right]
\]

Here, again, the homogeneous solution of \( \xi_2 \) is not periodic and therefore not of interest in this thesis.
and introducing this into the differential equation for $\dot{z}_2$, after equating coefficients of $\cos n\lambda$, note that

$$\frac{\partial h_0}{\partial t} + \lambda_T h_0 = -\frac{3}{2} \lambda_T \bar{g}_0$$

(64)

and

$$\frac{\partial h_n}{\partial t} + \lambda_{Tn} h_n = -\frac{3}{2} \lambda_T \bar{g}_n$$

(65)

The periodic solution to these expressions is

$$h_n(t) = -\frac{3}{2} \lambda_T \exp(-\lambda_{Tn} t) \left\{ \int_0^t \exp(\lambda_{Tn} t_1) \bar{g}_n(t_1) dt_1 + \frac{\exp(-\lambda_{Tn} L)}{1 - \exp(-\lambda_{Tn} L)} \int_0^L \exp(\lambda_{Tn} t_1) \bar{g}_n(t_1) dt_1 \right\}; \quad n \geq 0$$

(66)

In the general case the integrations, indicated for the solution of $T(\Lambda,t)$, must be performed numerically. This is of no great disadvantage since numerical integration requires fewer operations than would the evaluation of the closed form results.

One immediate application of this problem can be established as follows: The mean value of $\dot{z}_1^2$ is
\[ (\bar{\xi}_1^2)_m = (\bar{\alpha}_0)_m = \left( \alpha_0^2 + \frac{\alpha_1^2 + \alpha_2^2 + \alpha_3^2}{2} \right)_m \]

where \( \alpha_1 > \alpha_2 > \alpha_3 \). In many cases the approximation can be made that

\[ (\bar{\alpha}_0)_m \approx (\alpha_0^2)_m + \frac{1}{2}(\alpha_1^2)_m \]

where \( \alpha_0 \) is a time variant quantity and \( \alpha_1 \) measures the space variance (surface variance). The pure time variance can be approximated by

\[ (\Delta T_t) \approx T_{A0} \alpha_0 \]

and the pure surface variance can be approximated by

\[ (\Delta T_{surf, \max}) \approx T_{A0} (\alpha_1), \text{ for } (\cos \Lambda)_{\max} = 1 \]

so that

\[ (\bar{\alpha}_0)_m \approx \left( \frac{\Delta T_t^2}{T_{A0}} \right)_m + \frac{1}{2} \left( \frac{\Delta T_{surf, \max}^2}{T_{A0}} \right)_m \]

It is easy to prove that the mean value of \( \bar{\xi}_1 \) is zero, so that the mean temperature of the section in question is approximated by

\[ (T_A)_m \approx T_{A0} - \frac{3}{2} \left[ \frac{\Delta T_t^2}{T_{A0}} + \frac{1}{2} \frac{\Delta T_{surf, \max}^2}{T_{A0}} \right] \]

\[ = T_{A0} (1 + \bar{\xi}_2)_m \quad (67) \]
One should notice that $\Delta T_{surf, max}$, as defined in this problem, represents the largest temperature variance on the surface, but it is not equal to $\Delta T_{surf, mean}$, which is defined as

$$\Delta T_{surf, mean} = \left[ \frac{1}{2\pi} \int_0^{2\pi} \Delta T_{surf} \, d\lambda \right]^{1/2}$$

where

$$\Delta T_{surf} \simeq (\Delta T_{surf, max}) \cos \lambda$$

When these two definitions are combined it follows that

$$(\Delta T_{surf, mean})_m \simeq \frac{1}{2} (\Delta T_{surf, max})_m$$

and then the final form of equation (67) is

$$(T_\lambda)_m \simeq T_{\lambda_0} - \frac{3}{2} \left\{ \frac{(\Delta t^2)_m}{T_{\lambda_0}} + \frac{(\Delta T_{surf, mean})_m}{T_{\lambda_0}} \right\}$$

Equation (68) is in good agreement with equation (25) and shows how the time and space temperature variations combine to decrease $(T_\lambda)_m$.

The subscript $m$ in every case infers the operation

$$(z)_m = \frac{1}{L} \int_0^L (z) \, dt$$

has been performed on $z$. Equation (68) is in good agreement with equation (25) and shows how the time and space temperature variations combine to decrease $(T_\lambda)_m$. 
In order to show one important aspect of this result consider a body \( i \) which has thermal coupling with only one other body (body \( j \)). Also, let the \((mc)_i\) term approach infinity so that \( T_i \) is approximately a constant. Then equation (23), specialized for body \( i \), can be time integrated to yield

\[
\frac{1}{L} R_{i,j} \int_0^L (T_j - T_{Aj}) \, dt + \frac{1}{L} R_{i,j} \int_0^L (T_{Aj} - T_A) \, dt = 0
\]

and

\[
h_{i,j} = 0 \implies T_M = \frac{1}{L} \int_0^L T_{Aj} \, dt \simeq (T_{\Delta O})_j - \frac{3}{2}(2)_{j,n}(T_{\Delta O})_j
\]

with

\[
R_{i,j} = 0 \implies T_{\Delta i} = \left\{ \frac{1}{L} \int_0^L T_j \, dt \right\}^{1/2} \simeq (T_{\Delta O})_j
\]

Hence the temperature of body \( i \), for this simple case, is determined by the heat-transfer mode between body \( i \) and body \( j \).

In an earlier section (section I) it was shown that \( \lambda_T \) is the parameter governing the nondimensional temporal fluctuations when no space temperature variations exist. In the present section one finds that \( \lambda_T \) and \( \hat{\lambda}_T \) are a pair of parameters which, for a given set of \( \lambda_n(\delta) \), governs the nondimensional temperature variations when the temperature varies with both time and space.
The terms \( \lambda_T \) and \( f_n(t) / \dot{q} \) have already been defined; the quantity \( \lambda_T \) is a measure of heat conducted (inside the shell) divided by the mean heat content of the shell.

Most electronic equipment used by the aerospace industries is of the high density variety and (usually) quite sensitive to temperature. Often it is desirable to protect the electronic equipment from the severe temperature fluctuations which the spacecraft's external surfaces will see. This implies that (at least) during one orbital pass of the spacecraft around the earth the electronic equipment's temperatures will not have large fluctuations. The electronic gear will usually be housed in a given compartment and the temperature of this equipment may be partially controlled by its surrounding structure. It is evident from the discussion following equation (62) that the temperature of such equipment will be a function of not only the heat flux on the external surfaces of housing, but also the heat-transfer mode between the two sections. If this fact is neglected the resulting temperature error can be of the order of that caused by omitting the albedo heating effect. However, if no conductive heat transfer is present (into the spacecraft) and only radiative transfer used then the temperature fluctuations of the spacecraft's external surface is of no great consequence to the internal temperatures. Indeed for this case the analytical problem is reduced to the simple problem of solving the system of equations defined by equation (26). This task can be simplified by averaging equation (26) over one orbital pass. The result is a set of algebraic equations which are linear in \( T_i \) and can be solved by ordinary methods of matrix algebra.
Example of time-dependent temperature distributions.- An example of time-dependent temperature distributions is given below. The properties of the cylinder (the vehicle) chosen to illustrate this example are:

Cylinder thermal conductivity ($K$) = 0.135 Btu/min in. °R
Cylinder specific heat ($c$) = 0.21 Btu/°R lb
Cylinder density ($\rho$) = 0.0978 lb/in.³
Cylinder thermal diffusivity ($\alpha^2$) = 6.770 in.²/min
\[ \alpha = 2.602 \text{ in.}/(\text{min})^{1/2} \]
Radius of cylinder ($r$) = 15 in.
Thickness of cylinder shell ($T$) = 0.0625 in.
Solar absorptivity ($a_0$) = 0.60
Total hemispherical emissivity ($\varepsilon$) = 0.50

The orbital properties are:

Spin mode - long term
Solar orientation ($\eta_S$) = 0°
Orbit period $L = 100$ min
Time in direct sunlight ($L_1$) = 60 min

For this example, and for the sake of saving labor, the earth thermal radiation and the albedo heat have been neglected. This is not meant to imply that they are negligible; they are simply neglected in this one example case. Under these conditions equation (60) reduces to

\[ \dot{q}_R = \left( \frac{L_1}{L} \right) \left( 3a_0 \right) \bar{M}_0 \]
where \( \bar{M}_0 = a_0 = \frac{1}{2} \). It should be noted here that, in general, \( \bar{M}_0 \) is usually an approximation to \((A_\sigma/A)\); however, in this case it is the exact value.

Now

\[
S \approx 0.04968 \text{ Btu/in.}^2 \text{ min}
\]

thus

\[
T_{\lambda_0} = \left( \frac{\ln}{L} \right) \left( \frac{a_0}{\sigma} \right) \frac{A_\sigma}{A} \frac{S}{\sigma}
\]

\[
= \frac{1}{\pi} \left( \frac{0.65}{0.5} \right) (0.60) \left( \frac{0.04968}{2 \times 10^{-13}} \right) = 569.3 \times 10^3
\]

or

\[
T_{\lambda_0} = 488.5^\circ \text{ R}
\]

Hence,

\[
\hat{Q} = \tau p c T_{\lambda_0} = 0.0625(0.0978)(0.21)(488.5) \text{ Btu/in.}^2
\]

\[
= 0.627 \text{ Btu/in.}^2
\]

and

\[
\hat{q}_R = \Sigma \sigma T_{\lambda_0} = 0.5 \times 2 \times 10^{-13} \cdot 569.3 \times 10^3 = 0.00569 \text{ Btu/in.}^2 \text{ min}
\]

also

\[
\bar{m}_1 = a_1 = 0.500
\]

\[
\bar{m}_2 = a_2 = \frac{2}{3} \approx 0.2122
\]
\[ \bar{M}_4 = a_4 = -\frac{2}{\omega^2} \approx -0.0424 \]

In the following \( \bar{M}_4 \) can be safely neglected. Now

\[ \lambda_T = 4 \left( \frac{\partial R}{\partial Q} \right) = 0.0362 \text{ (min)}^{-1} \]

and

\[ \hat{\lambda}_T = \frac{K_T \tau_{0}}{r^2} = \frac{0.135 \times 0.0625 \times 588.5}{225} = 0.01886 \text{ Btu/ft}^2 \text{ min} \]

thus

\[ \lambda_{T1} = \frac{0.01886}{0.627} \text{ (min)}^{-1} = 0.0301 \text{ (min)}^{-1} \]

and so

\[ \hat{\lambda}_{T1} = 0.0362 + 0.0301 = 0.0663 \text{ (min)}^{-1} \]

\[ \hat{\lambda}_{T2} = 0.0362 + 0.124 = 0.1566 \text{ (min)}^{-1} \]

The time-dependent functions in equation (57) are given below

\[ \left\{ f_0(\delta_1) - (f_0)_{\infty} \right\} = \sigma_a \bar{M}_0 \left( H - \frac{\tau}{L} \right) \]

where \( H \) is one in the sunlight and zero when the spacecraft is in darkness. The coefficients of \( \cos \Lambda \) and \( \cos 2\Lambda \) in equation (57) simplify to
\[ f_1(\delta) = S a_0 \bar{M}_1 H \]
\[ f_2(\delta) = S a_0 \bar{M}_2 H \]

Thus

\[ (f_0(\delta_1) - f_0(\delta_2)) = 0.0948 \left( H - 0.60 \right) \text{Btu/in.}^2 \text{ min} \]

\[ f_1(\delta_1) = 0.1488 \text{ H Btu/in.}^2 \text{ min} \]

\[ f_2(\delta_1) = 0.0632 \text{ H Btu/in.}^2 \text{ min} \]

This completes all the necessary inputs to integrate the equation for \( dg/dt \). The results of this integration are plotted as figures 15(a), 15(b), and 15(c).

Next, the \( \bar{a}_n(t) \) can be calculated from equation (63), then equation (66) can be integrated. The values \( h_n(t) \) are plotted as figures 15(d), 15(e), and 15(f). These results can be used directly to calculate \( T(t, \Lambda) \), which, in turn, is plotted as figure 15(g) for the cases of

\[ \Lambda = 0^\circ \]
\[ \Lambda = 90^\circ \]
\[ \Lambda = 180^\circ \]

where \( \Lambda \) is the azimuth angle from a cylindrical polar coordinate system (measured zero when \( \eta_0 \) assumes its minimum value).
The values $g_n(t)$ were obtained by analytical integration while the $h_n(t)$ values were obtained by numerical integration.

This example is of particular interest since the properties are realistic and might be thought of as "typical of near-earth spacecraft." From figure 16(a) it can be seen that

$$\frac{1}{L} \int_0^L h_0(t)dt = 0.058$$

so that

$$(T_A)_m \approx 488.5 - 0.058 \times 488.5 = 488.5 - 26.3 = 460.2^\circ R$$

Now, if an electronic package was housed in this particular cylinder, and if the only heat which the package exchanged was with the cylinder (in this problem), then the temperature of the electronics package could seek one of two levels. If the heat exchanged to the electronic package was purely by radiation then the package would seek a temperature of $488.5^\circ R$. However, if the heat was transferred purely by conduction, the package would seek a temperature of $460.2^\circ R$. It is obvious then, why temperature variations must be investigated in cases such as this. Of the $28^\circ R$ temperature drop about $7^\circ$ is due to the time temperature variation; thus, in this case the circumferential variation is predominant.

In figure 15(g) it can be seen that when the spacecraft enters the sunlight the circumferential temperature variations grow rapidly. When the spacecraft enters the earth's shadow the temperature differences decrease rapidly.
In the literature problems of this type are commonly solved by employing a linear approximation for \( T^h \). This corresponds exactly to the accuracy achieved through \( T_0 (1 + \delta_1) \). From the plots in figures 15(a), 15(e), and 15(f) it is clear that \( T_0 \delta_2 \) can be appreciable. Also from the plot of \( h_0(t) \) in figure 15(d) it can be seen that the largest contribution from \( (T_0 \delta_2) \) is simply a negative constant.

It must be pointed out (here) that temperature fluctuations, as predicted by the linear approximation to \( T^h \), are generally good. The largest part of the temperature error comes from the fact that the mean value of the temperatures, found by this technique, is too high. It can be easily verified, by numerical integration, that solutions through an accuracy of \( T_0 + T_1 \) are not in equilibrium with their environment. That is to say, solutions of the linearized variety radiate more heat away than is received. Solutions through an accuracy of \( T_0 + T_1 + T_2 \) are in closer equilibrium with the surrounding environment.

Time-dependent temperature distribution solutions can be employed to show how a spacecraft might be divided into the minimum number of sections which permits the use of equation (26).

K. Solution of the Linear Heat Equation With Nonlinear Boundary Conditions

One-dimensional, time-dependent heat flow with a nonlinear radiation boundary is solved in this section.
Consider the heat conduction equation (eq. (1)). If \( p \) (power per unit volume of the conductor) is zero then

\[
\nabla^2 T = \frac{\rho c}{K} \frac{\partial T}{\partial t} = \frac{1}{\alpha^2} \frac{\partial T}{\partial t}
\]

where

\( \rho \) density of the body shell
\( c \) specific heat of the shell
\( K \) thermal conductivity of the shell

In the present problem it will be assumed that the heat conducted in a direction normal to the surface is very large compared to the heat conducted in the direction of the shell's tangent plane. Thus predominantly \( \nabla^2 T \) is expressed as

\[
\nabla^2 T \approx \frac{\partial^2 T}{\partial X^2}
\]

where \( X \) is measured in the surface normal direction and is zero at the back insulated face. When this approximation is applied, equation (1) simplifies to the well-known diffusion equation in one space variable

\[
\frac{\partial^2 T}{\partial X^2} = \frac{1}{\alpha^2} \frac{\partial T}{\partial t}
\]

the back face (\( X = 0 \)) is insulated, hence

\[
\frac{\partial T}{\partial X} = 0, \quad X = 0
\]

on the front face (\( X = \tau \))

\[
-K \frac{\partial T}{\partial X} = \Sigma\sigma T^4 - q(t), \quad X = \tau
\]
It has been shown, in several examples, that $q(t)$ is a periodic function. Guided by the previous analysis, it is assumed that

$$T(X,t) = T_0(X,t) + T_1(X,t) + T_2(X,t) + \ldots + \ldots$$

where the $T_i(X,t)$ are the modes of a perturbation solution to the governing differential equation.

Assuming the quantity $q(t)$ may be written as

$$q(t) = (q)_m + \left\{ q(t) - (q)_m \right\}$$

then the boundary condition can be expressed by

$$-k \left[ \frac{\partial T_0(t,\tau)}{\partial x} + \frac{\partial T_1(t,\tau)}{\partial x} + \frac{\partial T_2(t,\tau)}{\partial x} + \ldots \right] = \Sigma \left[ T_0^i(t,\tau) \right.$$

$$+ \, t_0^3(t,\tau)T_1(t,\tau)$$

$$+ \, t_0^3(t,\tau)T_2(t,\tau)$$

$$+ \, t_0^2(t,\tau)T_1^2(t,\tau)$$

$$+ \ldots \right] - (q)_m - \left\{ q(t) \right\} \right.$$  

$$- (q)_m \} \quad (69)$$

This expression will be satisfied at each order of magnitude if

$$T_0(t,X) = \text{const}$$
and

\[ \rho T_0^4 = (q)_m \]

hence

\[ -K \frac{\partial T_1(t, \tau)}{\partial x} - \sum \rho T_0^3(t, \tau) T_1(t, \tau) = -q(t) + (q)_m \quad (70) \]

and

\[ -K \frac{\partial T_2(t, \tau)}{\partial x} - \sum \rho T_0^3(t, \tau) T_2(t, \tau) = 46 \rho T_0^2(t, \tau) T_1^2(t, \tau) \quad (71) \]

Thus the nonlinear boundary condition can be satisfied by a system of linear relations. If the assumed solution is introduced into the diffusion equation it is apparent that

\[ \frac{\partial^2 T_i(t, x)}{\partial x^2} = \frac{1}{\alpha^2} \frac{\partial T_i(t, x)}{\partial t} \]

\[ \frac{\partial^2 T_2(t, x)}{\partial x^2} = \frac{1}{\alpha^2} \frac{\partial T_2(t, x)}{\partial t} \]

\[ . \]

\[ . \]

\[ . \]

and so on.

If the initial transient solution is of no interest then

\[ T_i(t, x) \] may be expressed as
\[ T_r(t, X) = \sum_{n=0}^{\infty} \left( f_{rn}(X) \sin n\omega t + g_{rn}(X) \cos n\omega t \right) \]  

(72)

where \( T_r \) is the \( r \)th mode of a perturbation solution to equation (1). This assumed solution, when introduced into the governing differential equation, becomes

\[ f''_{rn}(X) \sin n\omega t + g''_{rn}(X) \cos n\omega t = \left( \frac{n^2}{a^2} \right) f_{rn}(X) \cos n\omega t - \left( \frac{n^2}{a^2} \right) g_{rn}(X) \sin n\omega t \]

and since this expression must hold for all \( t \), then

\[ f''_{rn}(X) + \left( \frac{n^2}{a^2} \right) g_{rn}(X) = 0 \]

and

\[ g''_{rn}(X) - \left( \frac{n^2}{a^2} \right) f_{rn}(X) = 0 \]

where

\[ g''_{rn}(X) = \frac{d^2}{dX^2} g_{rn}(X) \]

and so on. Multiplying this last equation by \( i = \sqrt{-1} \) and adding to the former equation, then after some rearrangement, and setting

\[ \psi_{rn}(X) = (f_{rn} + ig_{rn}) \]

one finds that

\[ f''_{rn} - i\left( \frac{n^2}{a^2} \right) \psi_{rn} = 0 \]  

(73)
Now, let

\[ \omega_n = \frac{1}{\alpha} \sqrt{\frac{n^2}{2}} \]

then the solution to equation (73) is found to be

\[ \gamma_{\nu n}(x) = c_{\nu n} \cosh \omega_n (1 + i)x + d_{\nu n} \sinh \omega_n (1 + i)x \]

However, since no heat is to flow through the plane \( x = 0 \), \( d_{\nu n} = 0 \),

\[ \gamma_{\nu n}(x) = c_{\nu n} \cosh \omega_n (1 + i)x = (\hat{c}_{\nu n} + i\hat{\nu}_{\nu n}) \left\{ \cosh \omega_n x \cos \omega_n x \right. \\
+ \left. i \sinh \omega_n x \sin \omega_n x \right\} \]

Upon separating \( \gamma_{\nu n}(x) \) into its real and imaginary parts it follows that

\[ f_{\nu n}(x) = \hat{c}_{\nu n} \cosh \omega_n x \cos \omega_n x - \hat{\nu}_{\nu n} \sinh \omega_n x \sin \omega_n x \quad (74) \]

and

\[ g_{\nu n}(x) = \hat{\nu}_{\nu n} \cosh \omega_n x \cos \omega_n x + \hat{c}_{\nu n} \sinh \omega_n x \sin \omega_n x \quad (75) \]

Setting

\[ M_n(x) = \cosh \omega_n x \cos \omega_n x \]

\[ N_n(x) = \sinh \omega_n x \sin \omega_n x \]

it follows that if \( r \neq 0 \) then
\[ T_r(t,x) = \sum_{n=0}^{\infty} \left\{ \left[ \hat{c}_{rn} M_n(x) - \hat{c}_{rn} N_n(x) \right] \sin nt \right. \\
+ \left[ \hat{c}_{rn} M_n(x) + \hat{c}_{rn} N_n(x) \right] \cos nt \right\} \]  

(76)

The constants \( \hat{c}_{rn} \) and \( \hat{c}_{rn} \) will be found from the boundary conditions.

Expanding

\[ q(t) = q_m \]

in a complete Fourier series, that is

\[ q(t) = q_m = \sum_{n=0}^{\infty} \left\{ \hat{c}_{ln} \cos nt + \hat{c}_{ln} \sin nt \right\} \]  

(77)

and introducing this and equation (76) into equation (70), it follows that for each value of \( n \),

\[ K\left[ \hat{c}_{ln} M_n'(\tau) - \hat{c}_{ln} N_n'(\tau) \right] \sin nt + K\left[ \hat{c}_{ln} M_n'(\tau) + \hat{c}_{ln} N_n'(\tau) \right] \cos nt \]

\[ + (4\omega_0^2 \beta) \left[ \hat{c}_{ln} M_n(\tau) - \hat{c}_{ln} N_n(\tau) \right] \sin nt + (4\omega_0^2 \beta) \left[ \hat{c}_{ln} M_n(\tau) \right] \cos nt = \hat{c}_{ln} \cos nt + \hat{c}_{ln} \sin nt \]  

(78)

If this expression is separated into two parts (the coefficients of \( \sin nt \) and \( \cos nt \), respectively) the results can be written, in matrix form, as
where $M_n$, $M_n'$, $M_n''$, $M_n'''$ are evaluated at $X = \tau$. This expression determines $\hat{c}_{ln}$ and $\hat{c}_{ln'}$.

To determine $T_2(t,\tau)$, set $X = \tau$ in $T_1(t,\tau)$ and form

$T_2(t,\tau)$. Making the proper use of certain trigonometric identities $T_1^2(t,\tau)$ can be expressed as

$$+6\sigma T_0^2 T_1^2(t,\tau) = \sum_{n=0}^{\infty} \left( \hat{c}_{2n} \cos n\omega t + \hat{c}_{2n} \sin n\omega t \right)$$

Now noting that the equations expressing $T_2(t,\tau)$ and its boundary conditions have the identical form of $T_1(t,\tau)$, it is obvious that the equation for the unknown constants in $T_2(t,\tau)$ will be equation (79) with the subscript (1) changed to (2), hence

$$\begin{bmatrix} (K_n' + 4\Sigma \sigma T_0^3 M_n) & (K_n' + 4\Sigma \sigma T_0^3 M_n') \\ (K_n'' + 4\Sigma \sigma T_0^3 M_n) & (K_n'' + 4\Sigma \sigma T_0^3 M_n') \end{bmatrix} \begin{bmatrix} \hat{c}_{2n} \\ \hat{c}_{2n} \end{bmatrix} = \begin{bmatrix} \hat{c}_{2n} \\ \hat{c}_{2n} \end{bmatrix}$$

The unknown constants for all the $T_r(t,\tau)$ may be found in a similar manner, thus finally the solution of $T(t,\tau)$ is formed by

$$T(t,\tau) = T_0(t,\tau) + T_1(t,\tau) + T_2(t,\tau) + \ldots$$
One important feature of this solution lies in the fact that it can predict the temperature fluctuations of a thick wall structure which is exposed to radiative heat transfer on its front face. Therefore, it can also be used to justify the assumption necessary in arriving at equation (3).

Another interesting property can be found in the boundary conditions. From the boundary conditions for $T_1(t, X)$ it can be shown that

$$ (T_1(t, X))_m = 0 \quad \text{(The subscript } m \text{ denotes time average)} $$

Also since the back face is insulated

$$ \int_{t}^{t+L} \frac{\partial T_2(t, X)}{\partial X} \, dt = 0 \quad \text{(for all } X) \quad (\text{2}) $$

hence, the boundary condition on the front face becomes

$$ -K \int_{t}^{t+L} \frac{\partial T_2(t, \tau)}{\partial X} \, d\tau - \varepsilon \sigma (4 T_0^3) \int_{t}^{t+L} T_2(t, \tau) \, d\tau $$

$$ = 6 \varepsilon \sigma T_0^2 \int_{t}^{t+L} T_1^2(t, \tau) \, d\tau $$

or

$$ (T_2)_m = - \frac{3}{2} \left( \frac{T_1^2}{T_0} \right)_m $$

Thus from the assumed solution it is clear that
which is the usual temperature drop due to temporal fluctuations.

Example of diffusion equation with nonlinear boundary condition.

The numerical example given here illustrates temperature fluctuations on the face of a spacecraft's external surface, when the shell cannot be assumed to have a constant temperature through its thickness.

Suppose the shell in question is 1 inch thick and made of a foam plastic having the following properties:

Thermal conductivity ($K$) = 1.25 x $10^{-5}$ Btu/min · in. °R
Density ($\rho$) = 3.68 x $10^{-4}$ lb/in.$^3$
Specific heat ($c$) = 0.25 Btu/lb °R
Thermal diffusivity ($a^2$) = 0.0576 in.$^2$/min
Solar absorptivity ($\alpha_s$) = 0.3
Emissivity ($\varepsilon$) = 0.9
Thickness ($\tau$) = 1 inch

\[ q(t) = 0.3 \times 0.04968 \times 0.3 \times 0.04968 \cos \omega t \text{ Btu/in.}^2 \cdot \text{min} \]

Circular frequency of heat cycle ($\omega$) = 0.1256 radian/min
Period ($L$) = 50 minutes. Now, from equation (77)

\[ \hat{e}_{10} = 14.90 \times 10^{-3} \text{ Btu/min} \cdot \text{in.}^2 \]

\[ \hat{e}_{11} = 14.90 \times 10^{-3} \text{ Btu/min} \cdot \text{in.}^2 \]
and

\[ \omega_1 = \frac{1}{a} \sqrt{\frac{\Omega}{2}} = \left( \frac{1}{0.2399} \right) \left( \sqrt{\frac{0.1256}{2}} \right) = 1.0446 \text{ radians/in.} \]

From equation (66)

\[ T_0^{1/4} = \frac{(a)_{M}}{\xi_0} = 827.7 \times 10^3 \]

so that

\[ T_0 = 536.3^\circ \text{ R} \]

Also

\[ 4.26 T_0^3 = 4 \times 0.9 \times 2 \times 10^{-13} T_0^3 \]

\[ = 11.105 \times 10^{-5} \text{ Btu/ln.}^2 \text{ or min} \]

and

\[ \omega_1 \tau = 1.0446 \times 1 \times 1 = 1.0446 \text{ radians} \]

so that

\[ \cosh \omega_1 \tau = 1.5570 \]

\[ \sinh \omega_1 \tau = 1.2452 \]

\[ \cos \omega_1 \tau = 0.50227 \]

\[ \sin \omega_1 \tau = 0.36471 \]

thus

\[ K_1(\tau) = 1.5570 \]

\[ K_1'(-\tau) = \frac{d}{d\tau} \left( K_1 \right)_{\tau} = -0.7892 \]
\[ H_1(\tau) = 1.0767 \]

\[ H'_1(\tau) = \frac{d}{d\chi}(H_1)_{\chi=\tau} = 2.0950 \]

Now equation (79) gives

\[ \tilde{c}_{11} = 102.22 \]

\[ \hat{c}_{11} = 56.23 \]

From equations (74) and (75) it follows that

\[ f_{11}(\tau) = 21.4; f_{11}(0) = 102.22 \]

\[ \xi_{11}(\tau) = 151.7; \xi_{11}(0) = 56.23 \]

and from an application of equation (72)

\[ T_1(t, \tau) = 21.4 \sin \omega t + 151.2 \cos \omega t \]

\[ T_1(t, 0) = 102.2 \sin \omega t + 56.2 \cos \omega t \]

\[ T_1^2(t, \tau) = 11,659.6 + 1,617.8 \sin 2\omega t + 11,201.7 \cos 2\omega t \]

so that

\[ -6\omega T_0^2 T_1^2(t, \tau) = -34.3 \times 10^{-4} - 4.3 \times 10^{-4} \sin 2\omega t \]

\[ -33.5 \times 10^{-4} \cos 2\omega t \]

It is easy to see that the constant part of \(-6\omega T_0^2 T_1(t, \tau)\) produces a constant solution equal to

\[ \frac{-34.3 \times 10^{-4}}{4\omega T_0^2} = -33.3^0 \text{ R} \]
The remainder of the solution gives

\[ \hat{e}_{22} = -33.5 \times 10^{-4} \]
\[ e_{22} = -4.6 \times 10^{-4} \]

This completes the calculations for all the unknowns necessary to determine \( T_2(t, x) \); the procedure is identical to the calculation of \( T_1(t, x) \), so without further ado

\[ T_2(t, \tau) = -33.3 - 0.5 \sin 2\tau t - 28.2 \cos 2\tau t \]
\[ T_2(t, 0) = -33.3 - 12.4 \sin 2\tau t - 1.1 \cos 2\tau t \]

and the complete solution is, approximately, given by

\[ T(t, x) \approx T_0 + T_1(t, t) + T_2(t, x) \]

The solutions

\[ T_0 + T_1(t, \tau) \quad \text{and} \quad T_0 + T_1(t, \tau) + T_2(t, \tau) \]

are plotted in figure 16(b). The solutions

\[ T_0 + T_1(t, 0) \quad \text{and} \quad T_0 + T_1(t, 0) + T_2(t, 0) \]

are plotted in figure 16(a). In these figures it can be observed that the temperature on the insulated face has slightly lower temperature fluctuation, and lags the temperature on the surface \((x = \tau)\) by a few minutes. It is clear that this structure would not satisfy an assumption of constant temperature throughout the shell’s thickness.
On figure 16(b) the upper equilibrium temperature is plotted. The solution \( T_0 + T_1 \) rises well above this value and is therefore clearly in error. The solution \( T_0 + T_1 + T_2 \) falls just short of the upper limit and so in this sense \( (T_0 + T_1 + T_2) \) is a better solution than \( (T_0 + T_1) \).

L. Comparison of Exact and Approximate Solutions

The problem remaining is to compare the approximate solution with the exact solution. One of the few problems which possesses a closed form solution is that of a body with no spatial temperature gradient and heated by a constant heat flux. As an example of such a problem consider a small flat plate heated solely by the sun. For this case equation (2) becomes

\[
mc \frac{dT_A}{dt} = \varepsilon A_s a_s - \sigma \varepsilon T_A^4
\]

(E4)

Letting

\[
m = \sigma \varepsilon a_s; \quad \varepsilon A_s a_s = \sigma \varepsilon T_A^4
\]

then

\[
\frac{dT_A}{dt} = \left( \frac{T_A^4}{T_A^4 - T_\infty^4} - \frac{T_\infty^4}{T_A^4 - T_\infty^4} \right)
\]

(5)

and

\[
\frac{dT_A}{T_A^4 - T_\infty^4} = \frac{T_\infty^4}{c \varepsilon} dt
\]
which integrates to

$$\ln\left(\frac{T_A(t) + T_A(0)}{T_A(0) - T_A(t)}\right) = \frac{4\ln T_{\gamma}^3}{\rho c} t$$

where $T_A(0) = T_A(t)$ for $t = 0$.

If the sun does not heat the plate then the equation which governs its cooling is

$$\frac{dT_A}{T_A^4} = \frac{\rho g}{\rho c} dt$$

This can be integrated to provide

$$\left(\frac{1}{T_A^3(t)} - \frac{1}{T_A^3(0)}\right) = 3\frac{\rho g}{\rho c} t$$

For the perturbation solution of equation (84), it is assumed that

$$T_A = T_A^0 + T_A^1 + T_A^2 + \ldots$$

hence

$$T_A^4 = T_A^0 + 4T_A^0 T_A^1 + 6T_A^0 T_A^2 + 2T_A^0 T_A^1 + \ldots$$
When this assumption is introduced into equation (35) it is found that

\[ \hat{T}_{\Lambda_1} + \hat{T}_{\Lambda_2} + \ldots + \left( \frac{\Sigma \sigma}{\rho T_c} \right) \hat{T}_{\Lambda_0}^{-1} + \frac{4T_{\Lambda_0}}{\rho T_c} \hat{T}_{\Lambda_1} + \frac{4T_{\Lambda_0}}{\rho T_c} \hat{T}_{\Lambda_2} + 6T_{\Lambda_0}^2 \hat{T}_{\Lambda_1}^2 + \ldots \]

\[ = \left( \frac{\Sigma \sigma}{\rho T_c} \right) \hat{T}_{\Lambda_0}^{-1} \]

and, as usual, this can be separated into

\[ \hat{T}_{\Lambda_1} + \frac{4T_{\Lambda_0}}{\rho T_c} \left( \frac{\Sigma \sigma}{\rho T_c} \right) \hat{T}_{\Lambda_1} = 0; T_{\Lambda_1}(0) = \text{initial condition} \]

and

\[ \hat{T}_{\Lambda_2} + \frac{4T_{\Lambda_0}}{\rho T_c} \left( \frac{\Sigma \sigma}{\rho T_c} \right) \hat{T}_{\Lambda_2} = -6T_{\Lambda_0}^2 \left( \frac{\Sigma \sigma}{\rho T_c} \right) \hat{T}_{\Lambda_1}; T_{\Lambda_2}(0) = 0 \]

whose solutions are

\[ T_{\Lambda_1}(t) = T_{\Lambda_1}(0) \exp(-\lambda_T t); \lambda_T = \left( \frac{hT_{\Lambda_0}}{\rho T_c} \right) \frac{3 \Sigma \sigma}{\rho T_c} \]

and

\[ T_{\Lambda_2}(t) = \frac{2}{6} \left( \frac{T_{\Lambda_1}(0)}{T_{\Lambda_0}} \right) T_{\Lambda_1}(0) \left[ \exp(-2\lambda_T t) - \exp(-\lambda_T t) \right] \]

Finally, it is apparent that

\[ T_{\Lambda}(t) = T_{\Lambda_0} + T_{\Lambda_1}(0) \exp(-\lambda_T t) + \frac{2}{6} \left( \frac{T_{\Lambda_1}(0)}{T_{\Lambda_0}} \right) T_{\Lambda_1}(0) \left[ \exp(-2\lambda_T t) - \exp(-\lambda_T t) \right] \]

(36)
The approximation to equation (87) is obtained as follows:

Assume that

$$T_\Lambda = T_{\Lambda 0} + T_{\Lambda 1} + T_{\Lambda 2} + \ldots$$

then

$$0 \cdot T_{\Lambda 0} + 0 \cdot T_{\Lambda 1} + 0 \cdot T_{\Lambda 2} + \ldots + \left( \frac{\gamma a}{\rho c} \right) \left[ T_{\Lambda 0}^4 + 4T_{\Lambda 0}^3T_{\Lambda 1} + 4T_{\Lambda 0}^3T_{\Lambda 2} + 6T_{\Lambda 0}^2T_{\Lambda 1}^2 + \ldots \right] = 0$$

Now, let $T_{\Lambda 0} = T_\Lambda (0)$ so that

$$0 \cdot T_{\Lambda 1} + 4T_{\Lambda 0}^3 \left( \frac{\gamma a}{\rho c} \right) T_{\Lambda 1} = - \left( \frac{\gamma a}{\rho c} \right) T_{\Lambda 0}^4; \quad T_{\Lambda 1}(0) = 0$$

and

$$0 \cdot T_{\Lambda 2} + 4T_{\Lambda 0}^3 \left( \frac{\gamma a}{\rho c} \right) T_{\Lambda 2} = -6T_{\Lambda 0}^2 \left( \frac{\gamma a}{\rho c} \right) T_{\Lambda 1}^2; \quad T_{\Lambda 2}(0) = 0$$

With the accompanying solutions

$$T_{\Lambda 1} = \frac{1}{4} T_{\Lambda 0} \left[ \exp(-\lambda t) - 1 \right]$$

$$T_{\Lambda 2} = \frac{3}{16} T_{\Lambda 0} \left[ \exp(-\lambda t) - 1 \right] + \frac{3}{16} T_{\Lambda 0} \left[ \exp(-\lambda t) - 1 \right] \exp(-\lambda t)$$

$$+ \frac{3\lambda}{16} T_{\Lambda 0} \ t \ \exp(-\lambda t)$$

Thus it is evident that an approximate solution of the cooling curve is given by

$$T_\Lambda (t) \approx T_{\Lambda 0} + T_{\Lambda 1} + T_{\Lambda 2} \quad (89)$$
This example provides for a comparison between the exact solutions, equations (86) and (87), and the approximate solution, equations (88) and (89). The properties of the vehicle used in this example are the same as those for the body used in the example on time-dependent temperature distributions. The calculations are straightforward so that only the results are given here.

In figure 17(b) the heating curve, from $355^\circ R$ to the equilibrium temperature, $555^\circ R$, is presented. This represents the case of a thin walled cylinder spinning about its axis of symmetry. The heating source is the sun which sees the cylinder broadside. Initially, the cylinder has been cooled to $355^\circ R$ and then subjected to direct sunlight.

The curve marked $(T_{A0} + T_{A1} + T_{A2})$ is seen to be in good agreement with the exact solution. The curve marked $(T_{A0} + T_{A1})$ corresponds to the linearized solution and does not provide a very good comparison. In figure 17(a) the cylinder has been suddenly hidden from the sun, and the cooling curves (from $555^\circ R$) are shown. As before, the curve marked $(T_{A0} + T_{A1} + T_{A2})$ is in much better agreement with the exact solution than is the curve marked $(T_{A0} + T_{A1})$. In fact, adding the term $T_2$ almost doubles the range of applicability. Although no positive statement should be made from these results, figure 17(a) suggests that $(T_{A0} + T_{A1} + T_{A2})$ might be valid for variations of $T_{A1}$ up to about 25 percent of $T_{A0}$.

For periodic solutions this variance is above and below $T_0$, and for this case, the 25-percent variation now represents a 50-percent variation. This range of variance is usually sufficient for the thermal design of spacecraft.
It should be noted that the addition of more terms is not usually practical since the labor or calculating the higher modes increases rapidly. Even the inclusion of $T_{A_3}$ is usually too involved for practical purposes.

If the fluctuations of temperature are not too large, as compared to $(T_{A_0})$, then the series $T_{A_0} + T_{A_1} + T_{A_2} + \ldots$ converges to $T_A$. However, if the temperature fluctuations become large, as compared to $T_{A_0}$, then the sequence may not converge rapidly enough to be of any real use for thermal design purposes.

M. An Approach to the Passive Thermal Design of a Spacecraft

The purpose of this section is to bring together all the previously presented problems by means of a short discussion of one possible approach to achieve temperature control by a passive thermal design.

The thermal design of a typical spacecraft might be accomplished in the following manner. First one investigates the spin characteristics of the spacecraft. If the vehicle has two spin modes, as previously mentioned, then it is quite probable that only the "long term spin mode" needs to be considered at this stage.

The projected area of the spacecraft, referenced to the long term spin axis, should be averaged over one cycle of spin.

The functions $\mu(\eta)$ and $\hat{\mu}(\eta)$ can be calculated for every external section of the spacecraft. This allows for the calculation of $\hat{\mu}(\eta)_{\text{max}}$ and $\hat{\mu}(\eta)_{\text{min}}$. 
If the spacecraft's orbital elements are known then the quantity \((\cos \Omega)\) can be calculated.

Now, there could be three different temperature conditions to be designed for: mean temperatures, maximum temperatures, and minimum temperatures. The mean temperatures (of the external surfaces) generally govern the temperature of the spacecraft's internal components, such as electrical equipment and structure. The mean temperature, of at least one of the external surfaces, will be governed by the requirements of the spacecraft's electronics.

Equation (34) can be used to determine the orbital conditions which lead to the highest and lowest temperature levels in the internal structure and for the electronics section. If the mission demands that the spacecraft remains in operation for long periods of time it will in general be impossible to predict, before launch, what orientations (with respect to the sun) the spacecraft will encounter. Then, the designer must assume that every possible orientation might be realized. Here, equation (34) immediately leads the thermal designer to conditions which produce the highest and lowest temperatures for the internal structures and electronics package.

For the highest mean temperatures the conditions are:

\[
\hat{\mu}(\psi) = \hat{\mu}(\psi)_{\text{max}}
\]

\[
\frac{L_1}{L} = 1.00
\]

\[
\zeta = 0.0
\]
At first glance it appears that $\epsilon$ should be zero; but, under this condition it is impossible to achieve 100 percent time in sunlight ($L_1/L = 1$). Hence $\epsilon$ is chosen to be the smallest value which still permits ($L_1/L$) to equal unity.

For the lowest mean temperatures, the conditions are

$$\hat{\beta}(\eta) = \hat{\beta}(\eta)_{\text{min}}$$

$$\left(\frac{L_1}{L}\right) = \left(\frac{L_1}{L}\right)_{\text{min}}$$

$$\xi = \pi; \quad \epsilon = 0$$

These two sets of conditions will roughly determine the quantity $(a_{S_1}/L_1)$ for the ith section. In general there is no requirement which governs the values of $a_S$ and $\Sigma$ except the following considerations:

If $a_S$ and $\Sigma$ are large, then temperature fluctuations on the external surfaces are large. If $a_S$ and $\Sigma$ are very small, then the possible error in $(a_S/\Sigma)$ becomes large (because small values of $a_S$ and $\Sigma$ cannot be measured accurately) so absolute values of $a_S$ and $\Sigma$ are determined by a trade-off, values from 0.2 to 0.3 are usually acceptable. It should be remembered here that the individual case (heat radiators for example) can alter these requirements.

When the selection of $a_S$ and $\Sigma$ is made it will be clear whether or not a passive thermal control scheme is possible. If it is not possible to achieve the proper temperatures by a passive scheme, it should still be developed as far as possible since this will lessen the demands made on the active thermal control apparatus.
Once the $a_{c,i}$ and $\Sigma_i$ values have been chosen, tentatively, then solutions for the temperature distributions on the external surfaces can be found. These distributions refer to the case when each section is assumed to be isolated from its neighbors and can be calculated by the methods presented in this thesis. An exception, of course, is for the case of multiple reflections of light between adjacent surfaces. The previously mentioned solutions may not yield accurate temperature values where the assumption of isolated parts is in error. Therefore these procured can only be used to decide how sections of the spacecraft should be divided when solving the system of equations introduced by equation (26). This approach makes it possible to idealize the spacecraft into the minimum number of sections necessary to fulfill the assumptions made in arriving at equation (26).

The earlier selection of $a_{c,i}$ and $\Sigma_i$ values was made on the assumption that the spacecraft was spinning in its long-term spin mode. Should the spacecraft have two spin modes, then the desirable temperatures can be achieved during the short-time spin mode by restricting the allowable launch times.
VII. DISCUSSION AND RESULTS

A few of the problems which arise in the thermal design of spacecraft have been presented. In the literature it is commonly assumed that the nonlinear heat-transfer term \( T^n \) can be replaced by a linear approximation. This, unfortunately, omits the nonlinear characteristics of the solution and offers no method by which more accurate solutions can be obtained. For the problems studied in this thesis \( T_0 + T_1 \) corresponds exactly to the linearized solutions so often found in the literature.

The approach used in this thesis is, in reality, a method of successive approximations. Although \( T_0 \) has been chosen as a constant, this is not a necessary condition; in fact, the more closely \( T_0 \) approaches to \( T \) the quicker the sequence \( (T_0), (T_0 + T_1), (T_0 + T_1 + T_2) \ldots \) converges. In most cases, however, when \( T_0 \) is a variable, the calculation of the higher modes is extremely difficult and the author feels that a realistic compromise between complexity and the rapidity of convergence is afforded by taking \( T_0 \) to be a constant.

The numerical examples presented in this thesis were chosen because they primarily emphasize properties peculiar to the different problems.

In the discussion that follows, the more important ideas from each example are summarized, the discussion begins with section A.

In section A the classical heat-transfer equation is presented for three cases commonly confronted in the thermal design of
spacecraft. The first case occurs when the "space mean temperatures," of different sections of a spacecraft, are needed. The equation governing space mean temperatures, for any section of a spacecraft, is found to be a first-order nonlinear expression in $T^\text{th}$, when $T$ is temperature in degrees Rankine.

The second case investigated is that of a spacecraft with thin external shells which have uniform temperatures throughout the shell thickness. The equation governing this type of heat flow is found to be second order in two space variables, first order in the time variable, and nonlinear in $T^\text{th}$, where $T$ is again the temperature in degrees Rankine.

The third case given is that where no simplifying assumptions can be made. This type of heat flow is governed by the well-known "Diffusion Equation," with nonlinear boundary conditions.

Section D presents a simplified derivation of the radiation transfer equation. It is shown that the model used in section B produces diffuse radiation. All the radiative heat transfer investigated in this thesis is assumed to be diffuse.

The problem of calculating projected areas of spacecraft is attacked in section C. The projected area for a cone, with an arbitrary half angle, is calculated for the cone spinning about its axis of symmetry, and for the cone spinning about an axis normal to the axis of symmetry. It is stated in this section that the cone's area projections can be represented by Fourier cosine series.

In section D, the albedo and earth thermal energy, incident on a spacecraft of arbitrary shape, is calculated by the use of a
fourier cosine series. The projected area of the arbitrary body
is expressed as a cosine series and the integral governing the
radiant heat transfer (between the earth and spacecraft) is
integrated. Also, it is shown that heating of a spacecraft from
the earth's albedo can be approximated by the equation describing
the earth thermal energy incident on the vehicle.

The orientation angles, necessary to describe the different
heat fluxes incident on a spacecraft, are calculated in section E
by matrix methods. Also, simplified expressions for the orienta-
tion angles are given to aid the reader in visualizing a spacecraft's
motion relative to the sun and the earth.

In section F, a 'generalized finite difference equation' is
given for the spacecraft's heat transfer. It is pointed out that
this system of equations usually requires integration by digital
computers and, in these cases where large temperature variations
occur on the spacecraft's external surfaces, the labor may become
prohibitive.

A parametric study of orbital heating is given in section G.
This section presents a simplified study of albedo and earth thermal
heating, on an arbitrarily shaped spacecraft, which clearly points
out the most important variables connected with heat transfer
between the earth and the spacecraft. Also, an expression is
obtained which can be used to calculate the average equilibrium
temperature for any isolated section of the spacecraft.

A method useful for solving nonlinear differential equations
is given in section H. This method is introduced by assuming that
an approximate solution is known. The exact solution is then assumed to be the sum of the approximate solution plus a small perturbation value. This approach is pursued until it becomes evident that the exact solution can be obtained in the form of an infinite sequence of successive approximations. Finally, a method is suggested which allows direct determination of the linear differential equations which govern each successive approximation. No convergence proof for the infinite sequence is attempted.

In section I, a solution for the temperature time history of a spacecraft, with uniform temperatures, is established. From the solution it is found that the time-averaged temperature, of a spacecraft, is reduced by large temporal temperature fluctuations. A parameter, which governs the normalized temperature fluctuations is also found.

Temperature solutions are found for a cylinder, which has both temporal and space (temperature) fluctuations in section II. It is established from the solution that both the temporal and space temperature fluctuations reduce the average temperature of the cylinder. Finally, it is shown how the temperature of a body, enclosed by a second body, will tend to two different temperatures dependent on how heat from the first body is transferred to the second body. This last fact shows that neither the temperature of a spacecraft's internal structure nor its electronic package can be calculated without some knowledge of the (temperature) fluctuations on the spacecraft's external surfaces.

The perturbation method, used in this thesis, to solve the nonlinear differential equations, is used to obtain the solution of a linear
differential equation with nonlinear boundary conditions (in section K). The method is general, in its nature, and can be used to solve many other nonlinear problems. Its main usefulness lies in the fact that nonlinear problems, having no small perturbation parameter, can be solved by it.

Section L gives a comparison between the exact and approximate solutions to a nonlinear differential equation. The sole purpose of this section is to (roughly) indicate the accuracy of the perturbation scheme employed in this thesis. It is necessary that the comparison between the exact and approximate solutions be made since no convergence proof of the perturbation method has been established here. The numerical example given in section L suggests that the perturbation method employed through accuracy of

\[ T_0 + T_1 + T_2 \]

is acceptable for

\[ T_1 \leq \frac{1}{4} T_0 \]

Finally, section M outlines an approach to the problem of thermal design for spacecraft which use passive temperature control techniques.

Not all the problems encountered in the thermal design of spacecraft are discussed in this thesis. For example, the problem of multiple reflections between sections of a spacecraft has been carefully avoided. If one is interested in this problem, he should consult reference 3. The problem of multiple reflections is usually encountered when the radiation coefficients \( (R_{ij}) \) are being calculated.
Another problem commonly encountered in thermal design and not covered here, is the high resistance to conductive heat flow at the junctions between two bodies. If two bodies are held together by interface contact pressure only then their common boundary will, in general, have a very high resistance to conductive heat flow. The mode of heat transfer through these interfaces is not well understood and their heat-transfer characteristics are usually determined experimentally. Unfortunately, such experimental data are unreliable because of data scatter and the general inability to reproduce experimental results. The usual method of avoiding such interface connections is to resort to welding or bonding techniques. The silicon grease used for 'high vacuum' applications can also be used to greatly reduce interface resistance to heat flow. Interface resistance to conductive heat flow must be considered when calculating the 'conductive heat-transfer' coefficients \( h_{ij} \).

There are many other problems, of considerable importance in spacecraft thermal design, which cannot be mentioned here because of space limitations.

As a conclusion, some of the more important problems encountered in the spacecraft thermal design (but not realistically considered in the literature) have been solved without reference to a specific body shape whenever possible. Also, some solution methods for nonlinear problems (not having small perturbation parameters) are given.
VIII. ACKNOWLEDGMENTS

The author wishes to express his appreciation for the permission to use material in this thesis that was obtained from a research project conducted at the Langley Research Center of the National Aeronautics and Space Administration.

In particular, the author wishes to express his gratitude to Mrs. Beverly Latimer for the programming and running of the temperature time histories shown in figures 18(a) through 18(f); and to for evaluating the albedo integrals.

The author also wishes to express his gratitude to for preparing the thesis figures, and to for the many long hours spent in typing the manuscript.

He also wishes to thank , head of the Aerospace Engineering Department for his advice, patience, and open mind during the preparation of this thesis.

SOLUTIONS AND METHODS OF SOLUTIONS FOR PROBLEMS ENCOUNTERED IN THE THERMAL DESIGN OF SPACECRAFT

ABSTRACT

The analytical theory of the "passive thermal design of spacecraft" can be divided into two parts. The first part is concerned with the description of the radiant heat transfer to spacecraft external surfaces. The second part is concerned with calculating temperature over a spacecraft when the radiant heat incident, on the spacecraft's wall, is known.

The first part, the calculation of the heat incident on a spacecraft's external surfaces, has been investigated in the literature. References one, two, and three are examples of such papers. Unfortunately, the results of such papers are either numerical or else too specialized to be of general interest for the analytical study of the thermal design of spacecraft.

The second part, the calculation of temperatures over a spacecraft when the incident radiant heat is known, is also dealt with in the literature. References four and five are examples of such papers. The heat flow, occurring in the walls of spacecraft, is nonlinear because of thermal radiation and few exact solutions are known. This problem is usually attacked by "linearizing" the nonlinear term or by directly employing power series. The solution of the nonlinear heat equation by the linearization process is valid only for small temperature variations. When temperature differences are large, the linearized solutions do not properly account for the nonlinear radiation terms and
series error can result. When power series are employed directly to
solve the nonlinear heat flow equation, the labor required to solve
the time dependent problem is generally excessive because the elementary
functions cannot be used efficiently.

In this thesis, the radiant heat transferred to spacecraft is found
by the use of Fourier series. The resulting solutions are simple and
are valid for spacecraft of very general geometry. Heat transfer
calculations which previously required extensive integration on electronic
computers can be calculated by the results of this thesis with only trivial
labor. Also, the results have the advantage of being well suited for use
in the solution of the nonlinear heat transfer equation.

The problem of heat flow including nonlinear radiation is also
attached in this thesis. The method of solution used is closely related
to the well known method of successive approximations and allows solution
of nonlinear equations which do not have the classical "Small perturbation
parameter". Also, the method of solution used makes good use of the
elementary functions so that time dependent problems can be solved with-
out excessive labor. The problems solved in this thesis includes: the
temperature time history of a body at uniform temperature but exposed to
periodic radiative heating, the temperature time history of a body having
nonuniform temperatures and exposed to periodic radiative heating, and
finally the problem of linear heat flow with nonlinear boundary conditions.
In each case it is shown how linearized solutions neglect the important results of nonlinear radiation heat transfer.
