## VIRGINIA CORN PERFORMANCE TRIALS IN 1996

Performance trials of commercial corn hybrids were conducted at seven locations in Virginia in 1996. A list of the companies participating in the trials is shown in the table accompanying this information. At Mt. Holly, the hybrids were evaluated under irrigated and non-irrigated conditions. At Blackstone, all hybrids were thinned to achieve 18,000 and 22,000 plants/acre.

All hybrids entered in the Virginia trials were those submitted by commercial companies. The locations at which particular hybrids were entered were specified by the company. Companies entering hybrids were charged a fee for each hybrid per location to support the Corn Performance Trials.

All locations except Orange were planted with an Almaco two row plot planter at the desired population. Orange was planted by hand and thinned to the desired population. All locations except Orange were harvested with a Massey Ferguson 8-XP plot combine. Orange was hand harvested and shelled to obtain grain weights. Yields have been adjusted to 15.5% moisture.

The location at Smyth County was damaged by drought at silking and a severe storm before corn was mature. Yields were too variable and low to be meaningful in hybrid selection.

### Yield Differences

Experimental plots vary in yield and other measurements due to location in the field and other factors which cannot be controlled. Statistics given in the tables are intended to help the reader make valid comparisons between hybrids. The magnitude of differences which may have been due to uncontrollable variation has been computed for the data and listed at the bottom of columns as the LSD (.05) (least significant difference with 95% confidence). Differences less than the LSD are assumed not to be real differences with 95% confidence.

### Choice of Hybrids

When making hybrid selections it is important to realize that hybrids differ in their performance under different environments. Some hybrids are more adapted to a wide range of environments. Hybrid performance may vary with year and location variations in rainfall, temperature, pests and other environmental variables. In these experiments, many hybrids have essentially the same yield, and great care should be taken in interpreting the results of a single year's tests, especially at only one location. For these reasons it is important, whenever possible, to also look at a hybrid's average across locations when making hybrid selections. Multi-year averages give even greater confidence to hybrid performance decisions. The relative yield tables compare the yield of a hybrid to the average yield of all hybrids in the test. These tables are an excellent summary of hybrid yield potential compared to other hybrids.

*Appreciation is expressed to the Virginia Corn Check-Off Board  
for financial support of this research and the Virginia Extension  
corn program.*

\*Relative yield is calculated by dividing the yield of a hybrid by the average yield of all hybrids of all maturities at that location. A hybrid with a relative yield of 105 was 5% above the average of all hybrids at that location.

The corn hybrids at Blackstone were planted with four replications each of 18,000 and 22,000 plants/acre.
