Escalating global plastic pollution and the depletion of fossil-based resources underscore the urgent need for innovative end-of-life plastic management strategies in the context of a circular economy. Thermolysis is capable of upcycling end-of-life plastics to intermediate molecules suitable for downstream conversion to eventually high-value chemicals, but tuning the molar mass distribution of the products is challenging. Here we report a temperature-gradient thermolysis strategy for the conversion of polyethylene and polypropylene into hydrocarbons with tunable molar mass distributions. The whole thermolysis process is catalyst- and hydrogen-free. The thermolysis of polyethylene and polyethylene/polypropylene mixtures with tailored temperature gradients generated oil with an average chain length of $\sim C_{14}$. The oil featured a high concentration of synthetically useful α -olefins. Computational fluid dynamics simulations revealed that regulating the reactor wall temperature was the key to tuning the hydrocarbon distributions. Subsequent oxidation of the obtained α -olefins by sulfuric acid and neutralization by potassium hydroxide afforded sulfate detergents with excellent foaming behaviour and emulsifying capacity and low critical micelle concentration. Overall, this work provides a viable approach to producing value-added chemicals from end-of-life plastics, improving the circularity of the anthropogenic carbon cycle.

Plastic waste accumulation is a major environmental challenge facing the planet. Globally, 380 megatons of plastics are produced annually, and close to 75% are disposed of after a single use¹. Polyethylene (PE) and polypropylene (PP), in particular, account for 60% of all plastics and constitute a large proportion of discarded waste². To meaningfully disrupt the plastic waste accumulation trend and minimize carbon emissions, it is critical to increase the recycling rate and extend materials' service life in accordance with the Kyoto Protocols and Paris Accords³. Traditional strategies (for example, mechanical recycling) help close the plastic loop, but the quality of the regenerated plastics deteriorates, and market value decreases⁴. After a number of cycles, plastics reach the end of life. Using end-of-life plastics as an inexpensive feedstock

for producing value-added chemicals is therefore a highly attractive means to complement traditional approaches^{5–7}.

In this context, using end-of-life PE and PP as feedstock to produce other high-value chemicals is an enticing strategy⁸. Due to the chemical inertness of backbone $C(sp^3)-C(sp^3)$ bonds in PE and PP, elevated temperatures and long reaction times are required to pyrolyse these polyolefins⁹. For fuel uses, the pyrolysis oil must undergo additional hydrogenation¹⁰ for improved fuel quality. In addition, pyrolysis oil is a complex mixture of hydrocarbons that must be fractionated into naphtha and diesel range hydrocarbons to afford specific transportation fuel grades¹¹. A major technical challenge thus remains control over the chain length and its distribution. For lubricant and surfactant applications,

the hydrocarbon distribution requirement is even more stringent. Numerous strategies have been tested to control the hydrocarbon distribution, including zeolite-assisted pyrolysis and hydrocracking¹², hydrogenolysis¹³, catalytic hydrocracking¹⁴ and cross-alkane metathesis¹⁵ (Supplementary Scheme 1). Generally, these strategies rely on precious-metal catalysts (for example, Ir, Ru and Pt)¹⁶, high H₂ pressures (10–40 bar) and sometimes long reaction times to attain high oil yields, and the hydrocarbon distribution and functionality in the product cannot meet the downstream upcycling needs. Recently, we reported the conversion of PE and PP into intermediate waxes, followed by catalytic oxidation into fatty acids for hard soap¹⁷. This initial effort proves the concept of the ‘plastic-to-soap’ strategy, but challenges remain in controlling the hydrocarbon distribution of polyolefin thermolysis products and ensuring a high yield of functional terminal alkenyl groups. For industrial and household detergents and emulsifiers, surfactant molecules with chain lengths of C₁₂–C₁₄ are desired, which gives optimal performance^{18,19}.

Here, by controlling the thermolysis temperature gradient using a simple cooling design, we drastically shift the product hydrocarbon distribution from wax to oil and, importantly, achieve high α -olefin contents. The alkene-rich oil is upcycled into alkyl hydrogensulfates (AHS) through H₂SO₄ treatment followed by neutralization. As an alternative to fuel that has a short life cycle before being released as CO₂ into the atmosphere, AHS retain carbon in a reduced form and are high-value,

ubiquitous detergents and emulsifiers in industrial and household applications (Fig. 1e). Typically, AHS are manufactured from oleochemicals and petrochemicals²⁰. Using plastic waste as an alternative feedstock reduces the stress on global food resources and fossil fuels^{21–24}, representing a sustainable means to procure synthetic detergents.

Results

The key to hydrocarbon distribution control is the temperature gradient in our thermolysis process. In our design of temperature-gradient thermolysis, the gradient is controlled by setting the reactor bottom at a high temperature of T_1 and the reactor condenser walls at a lower temperature of T_2 . T_1 is sufficiently high to induce polymer chain scission, and T_2 is low enough to quench the chain scission reactions and condense the product. To control the product chain length, we hypothesize that we can simply tune T_2 in the condensation zone. In our previous report¹⁷, cold water circulation in the reactor played a critical role in ensuring that thermolysis did not predominantly produce gaseous products. This observation led us to explore the use of water as a coolant to modulate the temperature gradient and thus the molar mass of the degradation products.

Conversion of PE

To prove the concept, we first subjected high-density PE (HDPE; M_w , 88.38 kDa) to a thermolysis condition of $T_1 = 360\text{--}400\text{ °C}$ and $T_2 = 28\text{ °C}$

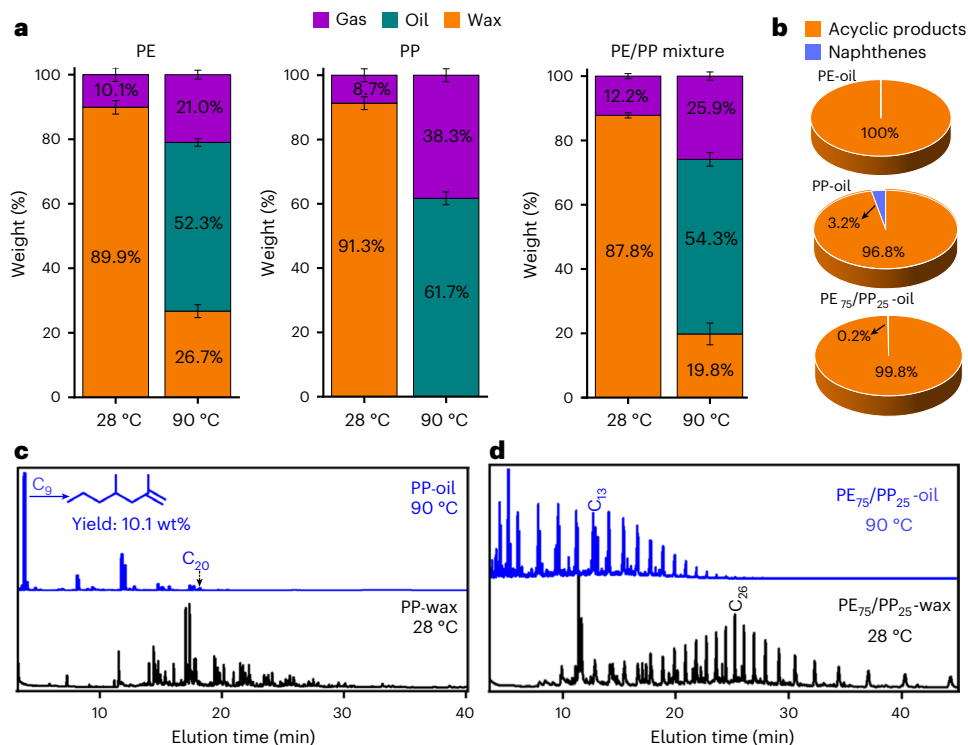

Fig. 2 | Tuning the molar mass of hydrocarbon products from PP and mixed PE₇₅/PP₂₅ thermolysis. a, Analysis and quantification of various product phases generated in the thermolysis reaction of PE, PP and a PE/PP mixture (weight ratio of HDPE/LDPE/LLDPE/PP, 25/25/25/25). The values in the bars represent the average yields from three experiments, and the error bars represent their

standard deviations. For thermolysis oils, the standard deviation was within $\pm 2.1\%$. **b**, The weight per cent distribution of naphthenes and acyclic products in PE, PP and PE₇₅/PP₂₅ thermolysis oil reveals a high concentration of acyclic alkenes and alkanes. **c,d**, GC traces of the oil and wax products from PP and the PE₇₅/PP₂₅ mixture under different reaction conditions.

by flowing room-temperature water in the reactor jacket (Fig. 1b, left). This degradation reaction afforded 89.9 wt% wax in the condensation zone consisting of both saturated and unsaturated hydrocarbons (Fig. 2a, left). The gas chromatogram (GC) of the wax in hot hexanes revealed a unimodal distribution centred at C₂₆ (Fig. 1d, black curve). In contrast, flowing hot water through the reactor jacket established a T₂ of -90 °C in the cold trap (Fig. 1b, right). The high T₂ resulted in a different temperature gradient, which furnished 52.3 wt% oil in the reactor headspace (Fig. 2a, PE at 90 °C; see also Supplementary Fig. 1a). Under the higher-T₂ condition, the components of the oil shifted to lower GC elution times, giving hydrocarbons centred at C₁₄ (Fig. 1d, red curve). Further characterization of the thermolysis oil by gas chromatography–mass spectrometry (GC–MS) revealed largely linear alkanes and alkenes along with minor dienes of C₇–C₂₀ (Supplementary Fig. 2), with small amounts of hydrocarbons >C₂₀. No cyclic or branched products were detected, suggesting negligible intramolecular and intermolecular radical recombinations under our reaction conditions²⁵. In addition to the oil, residual wax (~26.7 wt%) accumulated on the wall after a six-hour reaction. The residual wax revealed alkene and alkane compositions similar to wax collected under T₂ = 28 °C, as confirmed by GC. Besides oil and wax, PE thermolysis produced ~21.0 wt% gaseous products consisting mainly of propane, 2-butene and pentane (Supplementary Fig. 3). Presumably, the 90 °C cold trap liquefied the vaporized hydrocarbons and allowed them to flow back to the reactor bottom, creating a reflux-like phenomenon (Fig. 1g and Supplementary Fig. 4). The observed change in the oil-to-wax selectivity can thus be ascribed to the extensive chain cleavage as a result of ‘refluxing’ at T₁ = 360–400 °C.

Since it is challenging to precisely measure the temperature field in our reactors, we employed computational fluid dynamics simulations to furnish a detailed picture of this temperature field^{26–28}. When

T₂ = 28 °C (Fig. 1f), much of the reactor interior wall was at temperatures below the melting points of the wax products, measured to be -68.8–80.1 °C using a Buchi melting point instrument. As such, driven by diffusion and natural convection (Supplementary Fig. 5), the vaporized wax products were quenched and solidified upon contacting the cold walls. Raising T₂ to 90 °C substantially shrank the region of vertical walls at temperatures below 68.8 °C (Fig. 1g). Hence, vaporized hydrocarbons condensed into liquid on the reactor walls and flew back to the reactor bottom due to gravity (see the arrows in Fig. 1g), as confirmed by our experiments (Supplementary Fig. 4). The hydrocarbon products thus underwent further chain cleavage to produce lighter thermolysis oil. Notably, the temperature in the plastic melt changed by <4.7 °C when T₂ was raised from 28 °C to 90 °C (Fig. 1h, inset). The minor temperature changes in the plastic melt suggest that the tunability of the hydrocarbon chain length is probably not caused by the slight differences in the temperature within the melt layer but originates from the temperature field established in the reactor, especially on the reactor walls. The two reaction conditions demonstrate the potential of controlling the reactor jacket temperature to modulate the chain lengths of thermolysis products.

Further spectroscopic analysis of HDPE-derived hydrocarbons revealed a large amount of α -olefins, which are critical for downstream functionalization. The thermolysis at T₂ = 90 °C demonstrated a higher selectivity towards α -olefins in the oil (90.1 mol% α -olefins and 9.9 mol% internal olefins) than in the wax (78.7 mol% α -olefins and 21.3 mol% internal olefins) (Supplementary Table 1 and Supplementary Fig. 6a). The high selectivity towards terminal alkenes in the oil is probably caused by extensive β -scission, which shortens the product chain length and statistically promotes terminal alkene formation. This conjecture is supported by gel permeation chromatography (GPC) and high-temperature GPC (HT-GPC), which showed a number-averaged

Fig. 3 | Upcycling PE thermolysis oil into sulfate detergents. **a**, Scheme of the sulfation of alkene oils and subsequent neutralization to ionic detergents. rt, room temperature. **b**, ^1H NMR of HDPE oil sulfation in CDCl_3 . All terminal olefin

groups were fully reacted, as evidenced by the disappearance of the green and red proton signals in ^1H NMR. **c**, HSQC NMR of HDPE-oil AHS in CDCl_3 , highlighting the correlation pertaining to the sulfation reaction.

molar mass (M_n) of -180 g mol^{-1} for the oil versus 380 g mol^{-1} for the wax (Supplementary Table 2 and Supplementary Fig. 7b,c). Notably, the synthetically useful α -olefins in the thermolysis oil consisted of mostly diesel range hydrocarbons (Supplementary Fig. 6c), opening an opportunity for alternative fuel applications.

Conversion of PP and mixed plastics

Similar to HDPE, wax was the main product from PP thermolysis when $T_2 = 28 \text{ }^\circ\text{C}$ (Fig. 2a, middle). When we increased T_2 to $90 \text{ }^\circ\text{C}$, thermolysis oil emerged as the main product, giving a yield of 61.7%, similar to previous studies²⁹ at comparable temperatures (Fig. 2a, middle 'PP at $90 \text{ }^\circ\text{C}$ '; see also Supplementary Fig. 1b). The thermolysis oil contained predominantly 2,4-dimethyl-1-heptene ($-10.1 \text{ wt}\%$; Fig. 2c), a common trimer fragment (C_6) from PP degradation^{30,31}. Up to 38.3 wt% of PP was converted into gases, probably because PP has easily degradable tertiary C–C bonds. The gas phase was primarily composed of acyclic compounds, including propene, 2-butene and 2-methyl-1-pentene (Supplementary Fig. 8); 1,3,5-trimethylcyclohexane was the only gaseous cycloparaffin detected in the GC–MS. In the end, no wax was collected from the reactor. GC confirmed a narrower product distribution in the oil, mostly $\leq \text{C}_{20}$ light hydrocarbons (Fig. 2c). Additionally, GPC and HT-GPC validated the overall decrease in product molar mass upon elevating T_2 , showing an M_n of -565 g mol^{-1} for the wax and -250 g mol^{-1} for the oil (Supplementary Table 2 and Supplementary Fig. 7b,c). Altogether, these results uphold the practicality of varying temperature gradients in regulating the extent of chain scission in polyolefin thermolysis.

Like PE thermolysis, the alkenyl concentration ($c_{\text{C}=\text{C}}$) of PP-oil was substantially higher than that of PP-wax (6.75 mmol g^{-1} for PP-oil- $90 \text{ }^\circ\text{C}$ versus 4.61 mmol g^{-1} for PP-wax- $28 \text{ }^\circ\text{C}$; Supplementary Fig. 9a and Supplementary Table 1). Unlike PE, PP has methyl substitution at every second backbone carbon and offers thermodynamically stable carbon-centred radical intermediates and alkene scission products³². Thus, upon thermolysis, PP-oil exhibited higher $c_{\text{C}=\text{C}}$ than PE-oil. Temperature-gradient heating serves the dual purpose of improving alkenyl group concentration and modulating hydrocarbon distribution. Interestingly, most alkenes in PP-oil were acyclic α -olefins. Internal alkene signals were weak and broad (see ^1H nuclear

magnetic resonance (NMR) 4.9–5.5 ppm, Supplementary Fig. 9b), but in total, they accounted for -12.7% of the total alkenyl signals. Furthermore, GC–MS substantiated the predominance of α -olefins, and the most intense peaks corresponded to 2,4-dimethyl-1-heptene, 2,4-dimethyl-1-decene and 4,6,8-trimethyl-1-nonene (Supplementary Fig. 10). Even though PP-oil contained minor cyclic products, including 1,3,5-trimethylcyclohexane (Fig. 2b, middle; and Supplementary Fig. 10, products 3 and 9), acyclic alkenes and alkanes still comprised the majority of PP thermolysis oil.

Considering that real-world plastic waste is a complex mixture, we performed thermolysis of PE with varying amounts of PP. PE/PP mixtures are interesting because these two polyolefins can be easily isolated from other plastics³³ but are hard to separate from each other due to their comparable densities and chemical structures³⁴. A $\text{PE}_{75}/\text{PP}_{25}$ mixture of 25 wt% HDPE (milk jug), 25 wt% low-density PE (LDPE) (container lid), 25 wt% linear low-density PE (LLDPE) (commercial grade) and 25 wt% PP (centrifuge tube) was subject to thermolysis. The $\text{PE}_{75}/\text{PP}_{25}$ mixture provided a high wax yield of $-87.8 \text{ wt}\%$ when $T_2 = 28 \text{ }^\circ\text{C}$ and a $-54.3 \text{ wt}\%$ yield of oil as the major product when $T_2 = 90 \text{ }^\circ\text{C}$ (Fig. 2a, right). The gas phase under $T_2 = 90 \text{ }^\circ\text{C}$ accounted for $-25.9 \text{ wt}\%$ of the products and comprised light alkenes, including propene, 2-butene and minor $\geq \text{C}_5$ products (Supplementary Fig. 11). As established in single-polymer thermolysis, the hydrocarbon distribution shifted to lower molar masses upon increasing T_2 (Fig. 2d). This observation is further supported by GPC and HT-GPC, which revealed a lower M_n for the oil (-200 g mol^{-1}) than for the wax (-244 g mol^{-1}) from $\text{PE}_{75}/\text{PP}_{25}$ -mixture thermolysis (Supplementary Table 2 and Supplementary Fig. 7b,c).

The thermolysis of the $\text{PE}_{75}/\text{PP}_{25}$ mixture yielded products that were characteristic of PE and PP thermolysis. In addition to the typical PE thermolysis linear products, GC–MS revealed PP fragmentation compounds of methyl-substituted acyclic alkane and terminal alkenes (Supplementary Fig. 12). The presence of PP led to the generation of a small amount of cycloparaffins in the oil, such as 1,3,5-trimethylcyclohexane (Supplementary Fig. 12). The mixed-plastic-waste-derived oil exhibited slightly higher selectivity for α -olefins (93.4 mol%) than pure HDPE-oil (Supplementary Table 1). In addition, the mixed-plastic-waste-derived wax under $T_2 = 28 \text{ }^\circ\text{C}$ furnished 84.4 mol% α -olefins (Supplementary Table 1 and ^1H -NMR in Supplementary Fig. 13a).

In all cases, the contact angle decreased with increasing detergent concentration. **c**, Contact angle as a function of the PE-, PP-, PE₇₅/PP₂₅- or SDS-detergent concentration.

Upcycling to sulfate detergents

PE-oil and PP-oil can undergo functionalization to produce fatty acids, aldehydes, alcohols and various useful products^{35,36}. In this study, we targeted detergents, considering their high demand and market values (Fig. 1e). As a proof of concept, PE and PP thermolysis oils were converted into detergents in two steps. First, chilled oils were reacted with concentrated H₂SO₄ to produce AHS. The hydrogen sulfates were then neutralized with aqueous KOH (1 M) to generate ionic detergents (Fig. 3a). The addition of H₂SO₄ to PE-oil converted all α -alkenyls to AHS, as evidenced by the disappearance of the alkene peaks at 4.90–5.04 ppm and 5.82 ppm in ¹H NMR (Fig. 3b). The two new resonance peaks at 4.71 and 4.82 ppm—attributed to the Markovnikov and anti-Markovnikov products, respectively—were correlated to the carbon signals between 84.5 and 88.4 ppm in the 2D ¹H-¹³C heteronuclear single quantum coherence (HSQC) NMR (Fig. 3c). Different from the α -alkenyl groups, the minor internal alkenes were unaffected by the sulfation reaction, probably due to the mild reaction condition. Because alkene groups are present in many surfactant compounds and are beneficial for lathering and moisturizing properties³⁷, we did not pursue further sulfation of residual internal alkene groups. Similarly, the sulfation reaction effectively transformed PP-oil and PE₇₅/PP₂₅-oil into the corresponding AHS (Supplementary Figs. 14 and 15). The internal alkene groups (6.6 mol% in the mixed oil and 12.7 mol% in PP-oil) were unreacted, as detected in both 1D NMR and HSQC. Eventually, AHS were neutralized and basified with KOH until the pH reached ~9 before further characterization.

Detergent properties were investigated using a theta flow tensiometer and other surfactant analytical techniques. To determine the wettability (a characteristic of how well a surfactant solution spreads across a substrate), we measured the contact angles of a series of detergent concentrations (0 to 6.25 g l⁻¹) on a hydrophobic surface.

The hydrophobic surface was created by wrapping a strip of parafilm around a glass slide (Fig. 4a). For all PE-, PP- and PE₇₅/PP₂₅-detergents, the contact angle decreased with increasing detergent concentration (Fig. 4b). PE-detergents showed superior wettability compared with both the mixed and PP counterparts (Fig. 4c). The improved wettability is attributed to the favourable interactions between the detergents' alkyl chains and the hydrophobic parafilm chains at the interface. Conversely, the incorporation of methyl-substituted chains in PP-oil, mostly short-chain 2,4-dimethyl-1-heptene, hindered the same inter-chain interactions, probably because of the poor chain flexibility³⁸. The introduction of PP-derived molecules in the mixed detergent formulations therefore slightly worsened the wettability (Fig. 4b, red curve). Nevertheless, adequate wettability was maintained at PP loadings of up to 10 wt% (Supplementary Fig. 16). For comparison, commonly used sodium dodecyl sulfate (SDS) exhibited greater wettability than PP-derived detergent (Fig. 4c). However, PE and PE₇₅/PP₂₅-derived detergents outperformed SDS in terms of wettability. High PP loading in the feedstocks (>25%) results in detergents of poor wettability, probably because of the extensive substitution of the alkyl chains.

PE- and PE₇₅/PP₂₅-derived ionic detergents displayed excellent foaming behaviour and emulsifying capacity at room temperature. PE-detergent exhibited a well-sustained foamy lather over one hour (Fig. 5a, first row). In contrast, PP- and PE₇₅/PP₂₅-detergents could not sustain a stable foamy lather (Fig. 5a, second and third rows), presumably because of the defoaming characteristic of branched chains³⁹. Nonetheless, the low-foam feature of PP-detergent can be exploited to formulate PE/PP mixed surfactants presenting excellent wettability and defoaming performance for industrial applications⁴⁰. Furthermore, an effective detergent should have an affinity for both water and organic substances to achieve amphiphilicity. To determine the emulsifying power of the plastic-waste-derived detergents, we recorded the time for

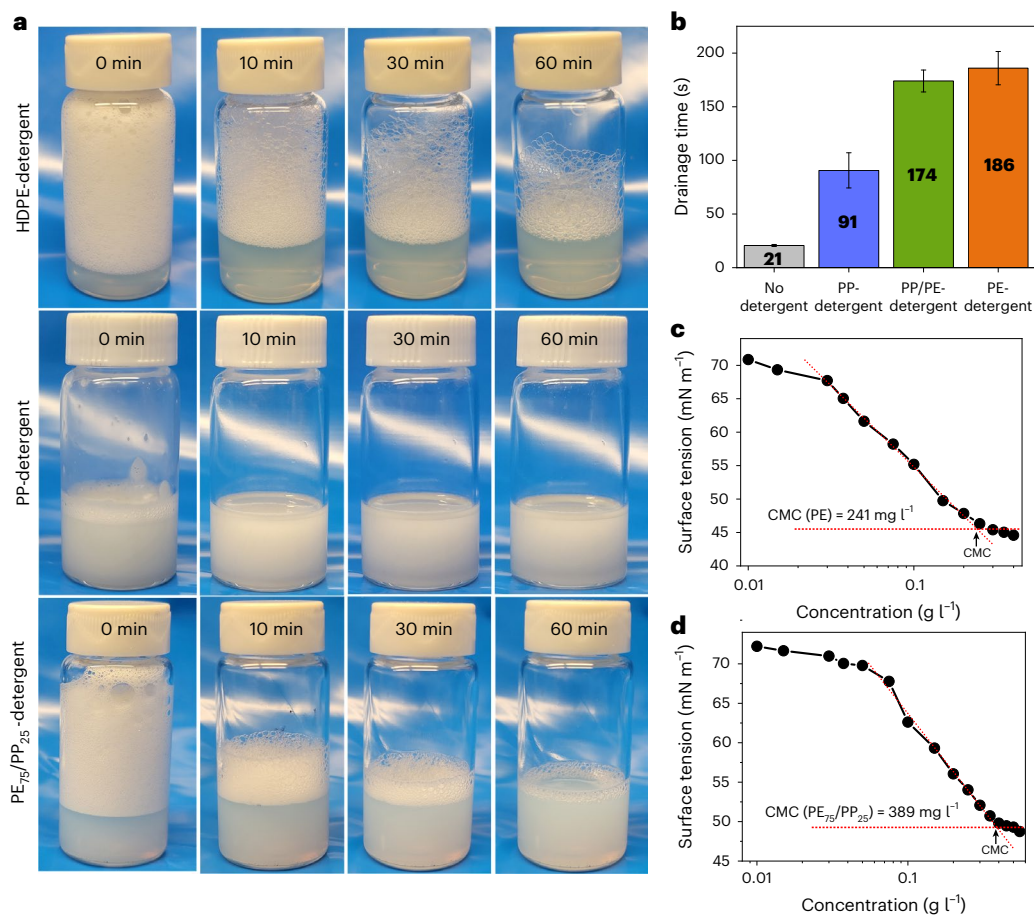

Fig. 5 | Physicochemical properties of sulfate detergents. a, Foam stability of HDPE-, PP- and PE₇₅/PP₂₅-derived detergents. HDPE-detergent exhibited higher foam stability than PP- or PE₇₅/PP₂₅-detergent. **b**, The emulsifying power of detergents was obtained by recording the separation time of 10 ml of water from

a mixture of paraffin oil and water. The values in the bars represent the average drainage time of three experiments, and the error bars represent their standard deviations. **c,d**, Surface tension as a function of PE-detergent concentration (**c**) and PE₇₅/PP₂₅-detergent concentration (**d**) to determine CMC.

10 ml of water to separate from a mixture of paraffin oil and water (foam drainage process; Supplementary Fig. 17)⁴¹. In the absence of a detergent, the separation was swift, and 21 s was sufficient to isolate 10 ml of water from the mixture (Fig. 5b). The addition of PP- or PE-detergent at a concentration of 1.25 mg ml⁻¹ drastically bolstered the drainage time to 91 s or 186 s, respectively. Remarkably, PE₇₅/PP₂₅-detergent also demonstrated great emulsification performance comparable to that of pure PE-detergent, illustrating the feasibility of turning unsorted mixed polyolefin wastes into sustainable emulsifiers. Besides paraffin oil, the detergent solutions (1.2 ml) mixed well with 50 μ l of hexanes, which further corroborates their excellent emulsification properties (Supplementary Fig. 18).

To study the detergents' ability to lower water surface tension (γ), we prepared a series of detergent solutions with varying concentrations and examined γ using a theta flow tensiometer in a pendant-drop mode. PE-detergent displayed a critical micelle concentration (CMC) of 241 mg l⁻¹ and exhibited the highest reduction in γ at the air–water interface ($\gamma_{\text{CMC}} = 45.5 \text{ mN m}^{-1}$; Fig. 5c). PP-detergent produced small changes in γ at low concentrations and only underwent micellization at higher concentrations ($\gamma_{\text{CMC}} = 51.6 \text{ mN m}^{-1}$, CMC = 518 mg l⁻¹; Supplementary Fig. 19a), as a consequence of poor hydrophobicity and aggregation of short alkyl chains⁴². Accordingly, the inclusion of 25 wt% PP in the PE₇₅/PP₂₅ mixture precursor led to a CMC value of 389 mg l⁻¹ and γ_{CMC} of 49.3 mN m⁻¹ for PE₇₅/PP₂₅-detergent (Fig. 5d). Nonetheless, detergents derived from mixed PE/PP waste containing up to 10 wt% PP still exhibited a high reduction in γ ($\gamma_{\text{CMC}} = 48.4 \text{ mN m}^{-1}$) at a relatively low CMC of 238 mg l⁻¹, on par with pure PE-detergent (Supplementary

Fig. 19b), which suggests the latter's ability to tolerate 'polymer contaminations'. Compared with some benchmark detergents, such as SDS (CMC > 2 g l⁻¹)⁴³, the CMC of PE- and PE/PP-mixture-derived detergents is lower, illustrating their excellent performance even at low concentrations.

Discussion

Over the past few decades, single-use plastics have continued to accumulate in the environment, and concerted efforts have been made to curb this pollution crisis. Using plastic waste as feedstocks to synthesize useful chemicals is among the most promising approaches. Our method herein employs underutilized plastic waste as a resource to generate high-value detergents. Modulating the temperature gradient in our custom-designed thermolysis reactor effectively adjusted the molar mass of hydrocarbons, enabling the production of thermolysis oils instead of waxes. We further valorized the hydrocarbon intermediates to furnish ionic detergents by reacting the olefins with H₂SO₄. All detergents displayed superior emulsifying power and substantially reduced the surface tension of the air–water interface at low detergent concentrations.

Compared with conventional hydrocracking strategies, our hydrogen-free thermolysis process produces substantial amounts of olefinic hydrocarbons that can be chemically transformed into high-value products^{44,45}. The relatively mild thermolysis conditions are key to minimizing the generation of low-value char and coke, typically seen for reactions at temperatures above 450 °C⁴⁶. To further improve the carbon efficiency and overall sustainability, it is essential to boost

the alkene-to-alkane ratio in the thermolysis products. Nonetheless, the saturated alkanes can be valorized into functional chemicals via oxidation using inorganic catalysts or microorganisms^{47,48}. Alternatively, the alkanes can be used directly as diesel fuel without additional hydrogenation⁴⁹. It is noteworthy that naphthenes observed in the PP-oil are allowed in diesel formulations, and they can make up >30% of the total composition⁵⁰. Future studies should also explore the possibility of upcycling into terminal AHS exclusively, which can be achieved through converting α -olefins into terminal fatty alcohols via hydroboration, followed by oxidation with air/SO₃. Terminal AHS may perform better than secondary AHS; however, the trade-off is that the synthesis involves more steps, thus potentially adding costs to large-scale production.

This work highlights a viable chemical upcycling strategy to obtain high-value products from plastic waste while contributing to the goal of achieving a circular economy. The presented methodology can potentially reduce the consumption of petrochemicals in detergent manufacturing. Compared with using plant-based oleochemicals (for example, agricultural fatty acids), the current process does not compete with food resources for raw materials or take up any agricultural land. A plastic-waste-based detergent industry does not exacerbate deforestation as do oleochemicals, and therefore presents a sustainable approach to accessing detergents. The use of cooling fluids to modulate the temperature gradient and control thermolysis product distributions demonstrates the versatility, effectiveness and practicality of our temperature-gradient thermolysis to procure detergent precursors from low-cost plastic waste resources.

Methods

Materials

Deuterated benzene (C₆D₆, 99.8%; Cambridge Isotope Laboratories), deuterated chloroform (CDCl₃, 99.8%; Cambridge Isotope Laboratories), sulfuric acid (98.0%; Fisher Scientific), hexanes (\geq 98.5%; VWR Chemicals), 1-dodecene (95%; Sigma-Aldrich), isopentane (\geq 99.5%; Sigma-Aldrich), *n*-decane (99%; Fisher Scientific), potassium hydroxide (pure pellets; Sigma-Aldrich), sodium hydroxide (pure pellets; Sigma-Aldrich), borane tetrahydrofuran complex solution (1.0 M in tetrahydrofuran (THF); Sigma-Aldrich) and hydrogen peroxide (30 wt%; Fisher Scientific) were purchased and used as received. HDPE (milk jug), LDPE (container lid) and PP (centrifuge tube) were obtained locally in Blacksburg, Virginia, followed by washing and air drying before pulverization. LLDPE pellets (commercial grade) were used without further purification. All polymers were pulverized into powders in a Homend pulverizer for 15 min (5 min, three times) before thermolysis.

Instrumentation

GC and flame ionization detector. Most GC analyses were carried out on a Hewlett Packard HP 5890 Series II Gas Chromatograph equipped with a DB-5 capillary column (30 m \times 0.25 mm \times 0.25 μ m) and a flame ionization detector. The following conditions were applied: helium column flow rate, 11 ml min⁻¹; injection port temperature, 280 °C; detector temperature, 280 °C; initial column temperature, 50 °C; ramp rate, 10 °C min⁻¹; final column temperature, 280 °C. The GC analyses in Supplementary Figs. 20–23 and 28–30 were carried out on an Agilent 7890A Gas Chromatograph System equipped with an HP-5 capillary column (30 m \times 0.32 mm \times 0.25 μ m) and a flame ionization detector. The following conditions were applied: carrier gas column flow rate, 11 ml min⁻¹; injection port temperature, 280 °C; detector temperature, 280 °C; initial column temperature, 40 °C; ramp rate, 10 °C min⁻¹; final column temperature, 280 °C. For sample preparation, typically, 10–15 mg of oil or wax was dissolved in 10 ml of hexanes or toluene. The oil solutions were stirred at room temperature until complete dissolution, and the waxes were stirred at 70 °C until all solids were dissolved. The samples were filtered through a 0.45 μ m PTFE filter, and 1 μ l of each

sample was injected into the GC. Triacontane was used as an internal standard for all weight fraction evaluations.

GC–MS. All GC–MS analyses were performed using a 6890 coupled with a 5973 MSD from Agilent. Separations were obtained using a DB-5 column (30 m, 250 μ m inner diameter (ID), with a film thickness of 0.25 μ m). The following operating conditions were used for the analyses:

Injection port temperature	280 °C
Split valve	1/25
Purge flow	3 ml min ⁻¹
Constant flow	1 ml min ⁻¹
Injection volume	1 μ l
Column oven initial temperature	50 °C
Column initial time	3 min
Column oven ramp rate	10 °C min ⁻¹
Column oven final time	280 °C
MS transfer line temperature	250 °C
MS database	Wiley
MS scan mod range	10–800

HT-GPC. HT-GPC of PE- and PP-derived waxes was performed using a Tosoh EcoSec HLC-8321 High-Temperature GPC System with an autosampler and a differential refractive index detector. The temperature settings were as follows: solvent stocker at 40 °C, pump oven at 50 °C, column oven at 160 °C, refractive index detector at 160 °C, injector valve at 160 °C and autosampler at 160 °C. The mobile phase was 1,2,4-trichlorobenzene (TCB) (Sigma Aldrich-HPLC Grade-256412). The TCB solvent was used as received, and no inhibitor was added. The sample columns were set to an operating flow rate of 1.0 ml min⁻¹, and the reference column was set to an operating flow rate of 0.5 ml min⁻¹. A 300 μ l sample loop was used for sample injection. Polymer separation was performed using four Tosoh TSKgel columns attached in the following order: one TSKgel guard column HHR (30) HT2 7.5 mm ID \times 7.5 cm (PN 22891), two TSKgel G2000 HHR (20) HT2 7.8 mm ID \times 30 cm columns (PN 22890) and one TSKgel GMHHR-H (S) HT2 7.8 mm ID \times 30 cm column (PN 22889). Tosoh 10 ml high-temperature sample vials with PTFE caps were used for sample preparation. 6–16 mg of sample was added to a 10 ml sample vial, and TCB solvent was then added to reach an end concentration of \sim 1.6 mg ml⁻¹. PE- and PP-derived waxes were heated at 160 °C for 1 h directly on the autosampler. The samples were not filtered. Tosoh's Polystyrene-Quick Kit-M (PN 21916) was used to create the calibration curve. The calibration curve was verified using Tosoh polystyrene F-10 (106 kDa–PN 05210) and Agilent polystyrene (700 Da–PN PSS-ps700) standards. The run time for all standards and samples was 60 min. For data analysis, Eco-Sec 8321 software (Tosoh) was used to evaluate the calibration curves and determine the molar mass and dispersity values. All polymer refractive index peaks were integrated from the point where they first deviated from the baseline to where the refractive index signal returned to the baseline again. Mark–Houwink correction values were used to determine PE and PP molar mass. The Mark–Houwink values used for polystyrene were $K = 12.1 \times 10^{-5} \text{ dl g}^{-1}$ and $\alpha = 0.707$. The Mark–Houwink values used for PE were $K = 40.6 \times 10^{-5} \text{ dl g}^{-1}$ and $\alpha = 0.725$. The Mark–Houwink values used for PP were $K = 19.0 \times 10^{-5} \text{ dl g}^{-1}$ and $\alpha = 0.725$.

Ambient-temperature GPC. To prevent the evaporation of oils at high temperatures, room-temperature GPC was used to characterize the molar masses of thermolysis oils. 15–20 mg of sample was dissolved in THF to achieve a concentration of \sim 2 mg ml⁻¹ and stirred for 30 min. The THF solution was filtered through a 0.2 μ m syringe filter into an HPLC

vial. 20 μl of sample was injected into an HPLC fitted with three PLgel 7.5 mm \times 300 mm columns in the series 10 μm \times 50 \AA , 10 μm \times 103 \AA and 10 μm \times 104 \AA (Agilent Technologies) at ambient temperature with an isocratic 1 ml min⁻¹ 100% THF (Sigma-Aldrich inhibitor-free, suitable for HPLC \geq 99.9%) for 40 min. Analytes are monitored at 210 nm, 260 nm and 270 nm on the diode-array detection.

NMR. All ¹H NMR experiments were performed at 298 K on a 500 MHz Bruker Avance II 500 spectrometer with 16 scans. All spectra were recorded using deuterated benzene and chloroform. ¹³C NMR experiments for oils were conducted at 298 K on a 500 MHz Bruker Avance II 500 spectrometer using a relaxation delay of 2 s and 1,024 scans. ¹³C NMR experiments for AHS were performed using a relaxation delay of 6 s and 3,072 scans. 2D-HSQC was conducted at 298 K on a 500 MHz Bruker Avance III 500 spectrometer with a relaxation time of 2 s, 16 scans and a digitizing increment of 400.

Theta flow tensiometer. Contact angle and surface tension were measured at room temperature on a Biolin Scientific theta flow tensiometer. Contact angle experiments were performed in a sessile drop mode with a drop volume of -5 μl , a drop rate of 1 $\mu\text{l s}^{-1}$ and a run time of -10 s. Surface tensions were evaluated in a pendant drop mode with a drop volume of -10 μl , a drop rate of 1 $\mu\text{l s}^{-1}$ and a run time of -10 s.

Thermolysis procedures

Typically, 1.5 g of pulverized HDPE (particle size, 2.7 mm) or PP (particle size, 1.6 mm) was loaded into a custom-designed quartz reactor and purged with nitrogen at 200 °C for 15 min. After purging, the temperature was slowly ramped (rate, 20 °C min⁻¹) to the operational temperature range (the top layer of the plastic melt was -360 °C). At the same time, room-temperature water or heated water was circulated in the reactor jacket. After 10 min, the cold-zone temperature stabilized at -28 °C or -90 °C. The thermolysis lasted for 6 h for HDPE and 2 h for PP. After completion, the thermolysis oil in the headspace was collected using a glass pipette and weighed on an analytical balance. Solid wax was extracted from the reactor with hexanes twice (10 ml each), dried under vacuum and weighed to determine the yield.

To upcycle PE- and PP-oil to sulfate detergents, 100 mg of each oil was weighed and transferred to a flame-dried 25 ml vial fitted with a stir bar. The test tube was set in a cold bath at 0 °C, and 50 mg of concentrated sulfuric acid was added dropwise while stirring. For PP-oil, 86.7 mg of H₂SO₄ was used. After 10 min, the vial and its contents were stirred at room temperature for 10 min and then neutralized with 1 M KOH solution (1.2 ml) to afford the ionic detergents. The detergent solutions were diluted with DI water to a total volume of 8 ml. The unconverted alkane component was isolated by washing the crude solution with hexanes (5 ml, 3 \times). The combined hexane extracts were dried over Na₂SO₄, concentrated under vacuum and weighed. An aliquot of the sample was subject to GC and GC-MS characterization. To remove any residual hexanes in the purified detergent solution, a moderate vacuum of 300 mmHg was applied to the detergent vial at 45 °C for 10 min.

Alternatively, selective upcycling of the thermolysis oils to terminal fatty alcohols was accomplished through hydroboration. Typically, 500 mg of PE-oil (-1.9 mmol of alkene, 1 eq.) was added to a two-neck round-bottom flask equipped with a stir bar. The flask was purged with nitrogen and transferred to an ice-water bath. Then, 4.0 ml (-4.0 mmol, 2.1 eq.) of borane tetrahydrofuran complex solution (BH₃·THF, 1.0 M in THF) was dispensed into the flask over a 30-minute period. The flask was warmed to room temperature and stirred for 2 h. Excess BH₃·THF was decomposed by adding 1 ml of DI water until bubbling stopped. The flask was placed back into an ice-water bath. Then, 5.4 ml of 3 M NaOH and 5.4 ml of H₂O₂ (30 wt%) were added dropwise sequentially. The flask was allowed to warm to room temperature and stirred overnight. After completion, the solution was worked up in a separatory funnel

using ether and DI water (30 ml each). The water layer was extracted with additional ether (10 ml, 2 \times) to recover any residual fatty alcohols. The combined organic layer was washed with DI water (50 ml, 3 \times). The ether extracts were dried over Na₂SO₄, concentrated under vacuum and characterized with NMR and Fourier transform infrared spectroscopy. PP- and PE₇₅/PP₂₅-derived fatty alcohols were prepared similarly.

Simulations

Computational fluid dynamics (CFD) simulations were conducted to analyze the fluid flow and heat transfer within the reactor. The meshing was carried out using ANSYS ICEM CFD 2023 R2, and the simulations were performed using ANSYS FLUENT 2023 R2. Detailed descriptions of the physical models, numerical setup, and simulation parameters can be found in the supplementary information.

Reporting summary

Further information on research design is available in the Nature Portfolio Reporting Summary linked to this article.

Data availability

Additional data are provided in the Supplementary Information, and all the raw files are available via Dryad at <https://doi.org/10.5061/dryad.4InsIrnq0> (ref. 51). Source data are provided with this paper.

Acknowledgements

This work is based on the project supported by NSF Award No. DMR-2411680. We acknowledge the Chemistry Chromatography Center at Virginia Tech and M. Ashraf-Khorassani for providing assistance with the GC–MS experiments.

Author contributions

G.L. conceived and supervised the project. G.L. and N.E.M. designed the research. N.E.M. performed the thermolysis and sulfation

experiments. J.M., L.S. and N.R. evaluated the molar masses of the plastic feedstocks and thermolysis products. N.E.M. and A.D. conducted materials characterization of plastic waste-based detergents. R.Q. and R.J. performed the computational fluid dynamics studies. G.L. and N.E.M. wrote the original manuscript. All authors contributed to manuscript proofreading and editing.

Competing interests

G.L. and N.E.M. have filed a patent based on this work: PCT/US2024/026720. The remaining authors declare no competing interests.

Reporting Summary

Nature Portfolio wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Portfolio policies, see our [Editorial Policies](#) and the [Editorial Policy Checklist](#).

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

- | n/a | Confirmed |
|-------------------------------------|--|
| <input type="checkbox"/> | <input checked="" type="checkbox"/> The exact sample size (n) for each experimental group/condition, given as a discrete number and unit of measurement |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly |
| <input checked="" type="checkbox"/> | <input type="checkbox"/> The statistical test(s) used AND whether they are one- or two-sided
<i>Only common tests should be described solely by name; describe more complex techniques in the Methods section.</i> |
| <input checked="" type="checkbox"/> | <input type="checkbox"/> A description of all covariates tested |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals) |
| <input checked="" type="checkbox"/> | <input type="checkbox"/> For null hypothesis testing, the test statistic (e.g. F , t , r) with confidence intervals, effect sizes, degrees of freedom and P value noted
<i>Give P values as exact values whenever suitable.</i> |
| <input checked="" type="checkbox"/> | <input type="checkbox"/> For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings |
| <input checked="" type="checkbox"/> | <input type="checkbox"/> For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes |
| <input checked="" type="checkbox"/> | <input type="checkbox"/> Estimates of effect sizes (e.g. Cohen's d , Pearson's r), indicating how they were calculated |

Our web collection on [statistics for biologists](#) contains articles on many of the points above.

Software and code

Policy information about [availability of computer code](#)

Data collection

Data analysis

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors and reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Portfolio [guidelines for submitting code & software](#) for further information.

Data

Policy information about [availability of data](#)

All manuscripts must include a [data availability statement](#). This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A description of any restrictions on data availability
- For clinical datasets or third party data, please ensure that the statement adheres to our [policy](#)

Human research participants

Policy information about [studies involving human research participants and Sex and Gender in Research](#).

Reporting on sex and gender

Use the terms *sex* (biological attribute) and *gender* (shaped by social and cultural circumstances) carefully in order to avoid confusing both terms. Indicate if findings apply to only one sex or gender; describe whether sex and gender were considered in study design whether sex and/or gender was determined based on self-reporting or assigned and methods used. Provide in the source data disaggregated sex and gender data where this information has been collected, and consent has been obtained for sharing of individual-level data; provide overall numbers in this Reporting Summary. Please state if this information has not been collected. Report sex- and gender-based analyses where performed, justify reasons for lack of sex- and gender-based analysis.

Population characteristics

Describe the covariate-relevant population characteristics of the human research participants (e.g. age, genotypic information, past and current diagnosis and treatment categories). If you filled out the behavioural & social sciences study design questions and have nothing to add here, write "See above."

Recruitment

Describe how participants were recruited. Outline any potential self-selection bias or other biases that may be present and how these are likely to impact results.

Ethics oversight

Identify the organization(s) that approved the study protocol.

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

Life sciences Behavioural & social sciences Ecological, evolutionary & environmental sciences

For a reference copy of the document with all sections, see [nature.com/documents/nr-reporting-summary-flat.pdf](https://www.nature.com/documents/nr-reporting-summary-flat.pdf)

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

Sample size

Describe how sample size was determined, detailing any statistical methods used to predetermine sample size OR if no sample-size calculation was performed, describe how sample sizes were chosen and provide a rationale for why these sample sizes are sufficient.

Data exclusions

Describe any data exclusions. If no data were excluded from the analyses, state so OR if data were excluded, describe the exclusions and the rationale behind them, indicating whether exclusion criteria were pre-established.

Replication

Describe the measures taken to verify the reproducibility of the experimental findings. If all attempts at replication were successful, confirm this OR if there are any findings that were not replicated or cannot be reproduced, note this and describe why.

Randomization

Describe how samples/organisms/participants were allocated into experimental groups. If allocation was not random, describe how covariates were controlled OR if this is not relevant to your study, explain why.

Blinding

Describe whether the investigators were blinded to group allocation during data collection and/or analysis. If blinding was not possible, describe why OR explain why blinding was not relevant to your study.

Behavioural & social sciences study design

All studies must disclose on these points even when the disclosure is negative.

Study description

Briefly describe the study type including whether data are quantitative, qualitative, or mixed-methods (e.g. qualitative cross-sectional, quantitative experimental, mixed-methods case study).

Research sample

State the research sample (e.g. Harvard university undergraduates, villagers in rural India) and provide relevant demographic information (e.g. age, sex) and indicate whether the sample is representative. Provide a rationale for the study sample chosen. For studies involving existing datasets, please describe the dataset and source.

Sampling strategy

Describe the sampling procedure (e.g. random, snowball, stratified, convenience). Describe the statistical methods that were used to predetermine sample size OR if no sample-size calculation was performed, describe how sample sizes were chosen and provide a rationale for why these sample sizes are sufficient. For qualitative data, please indicate whether data saturation was considered, and what criteria were used to decide that no further sampling was needed.

Data collection	<i>Provide details about the data collection procedure, including the instruments or devices used to record the data (e.g. pen and paper, computer, eye tracker, video or audio equipment) whether anyone was present besides the participant(s) and the researcher, and whether the researcher was blind to experimental condition and/or the study hypothesis during data collection.</i>
Timing	<i>Indicate the start and stop dates of data collection. If there is a gap between collection periods, state the dates for each sample cohort.</i>
Data exclusions	<i>If no data were excluded from the analyses, state so OR if data were excluded, provide the exact number of exclusions and the rationale behind them, indicating whether exclusion criteria were pre-established.</i>
Non-participation	<i>State how many participants dropped out/declined participation and the reason(s) given OR provide response rate OR state that no participants dropped out/declined participation.</i>
Randomization	<i>If participants were not allocated into experimental groups, state so OR describe how participants were allocated to groups, and if allocation was not random, describe how covariates were controlled.</i>

Ecological, evolutionary & environmental sciences study design

All studies must disclose on these points even when the disclosure is negative.

Study description	<i>Briefly describe the study. For quantitative data include treatment factors and interactions, design structure (e.g. factorial, nested, hierarchical), nature and number of experimental units and replicates.</i>
Research sample	<i>Describe the research sample (e.g. a group of tagged <i>Passer domesticus</i>, all <i>Stenocereus thurberi</i> within Organ Pipe Cactus National Monument), and provide a rationale for the sample choice. When relevant, describe the organism taxa, source, sex, age range and any manipulations. State what population the sample is meant to represent when applicable. For studies involving existing datasets, describe the data and its source.</i>
Sampling strategy	<i>Note the sampling procedure. Describe the statistical methods that were used to predetermine sample size OR if no sample-size calculation was performed, describe how sample sizes were chosen and provide a rationale for why these sample sizes are sufficient.</i>
Data collection	<i>Describe the data collection procedure, including who recorded the data and how.</i>
Timing and spatial scale	<i>Indicate the start and stop dates of data collection, noting the frequency and periodicity of sampling and providing a rationale for these choices. If there is a gap between collection periods, state the dates for each sample cohort. Specify the spatial scale from which the data are taken</i>
Data exclusions	<i>If no data were excluded from the analyses, state so OR if data were excluded, describe the exclusions and the rationale behind them, indicating whether exclusion criteria were pre-established.</i>
Reproducibility	<i>Describe the measures taken to verify the reproducibility of experimental findings. For each experiment, note whether any attempts to repeat the experiment failed OR state that all attempts to repeat the experiment were successful.</i>
Randomization	<i>Describe how samples/organisms/participants were allocated into groups. If allocation was not random, describe how covariates were controlled. If this is not relevant to your study, explain why.</i>
Blinding	<i>Describe the extent of blinding used during data acquisition and analysis. If blinding was not possible, describe why OR explain why blinding was not relevant to your study.</i>

Did the study involve field work? Yes No

Field work, collection and transport

Field conditions	<i>Describe the study conditions for field work, providing relevant parameters (e.g. temperature, rainfall).</i>
Location	<i>State the location of the sampling or experiment, providing relevant parameters (e.g. latitude and longitude, elevation, water depth).</i>
Access & import/export	<i>Describe the efforts you have made to access habitats and to collect and import/export your samples in a responsible manner and in compliance with local, national and international laws, noting any permits that were obtained (give the name of the issuing authority, the date of issue, and any identifying information).</i>
Disturbance	<i>Describe any disturbance caused by the study and how it was minimized.</i>

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

Materials & experimental systems

n/a	Involvement in the study
<input checked="" type="checkbox"/>	<input type="checkbox"/> Antibodies
<input checked="" type="checkbox"/>	<input type="checkbox"/> Eukaryotic cell lines
<input checked="" type="checkbox"/>	<input type="checkbox"/> Palaeontology and archaeology
<input checked="" type="checkbox"/>	<input type="checkbox"/> Animals and other organisms
<input checked="" type="checkbox"/>	<input type="checkbox"/> Clinical data
<input checked="" type="checkbox"/>	<input type="checkbox"/> Dual use research of concern

Methods

n/a	Involvement in the study
<input checked="" type="checkbox"/>	<input type="checkbox"/> ChIP-seq
<input checked="" type="checkbox"/>	<input type="checkbox"/> Flow cytometry
<input checked="" type="checkbox"/>	<input type="checkbox"/> MRI-based neuroimaging
