A Study on the Long-Term Performance of Seepage Barriers in Dams

John D. Rice

ABSTRACT

In a vast majority of cases, seepage barriers increase the reliability of dams. However, it is important to recognize that seepage barriers often drastically increase hydraulic gradients around the boundaries of the barrier, and through any windows or defects in the barrier. The result is increased water pressures and hydraulic gradients behind and around the barrier. These increased pressures and gradients have potential to provide the catalyst for initiation of several modes of internal erosion that were either unlikely or less likely without the seepage barrier. As a consequence, seepage barriers give rise to the potential for additional mechanisms of internal erosion and piping in the dam and the foundation.

Mechanisms of erosion and piping that are uniquely related to seepage barriers have been investigated through review of measured performance of existing dams, and through analytical studies. A compendium of 30 case studies of dams that have had seepage barriers in place for over 10 years has been assembled, and observations and insights garnered from these case studies were compiled. Finite element seepage and deformation analyses have been performed to provide better understanding of the performance of seepage barriers and the mechanisms that affect their performance. Based on the findings from the case studies and analyses, potential failure modes specific to dams with seepage barriers were identified, and the sequences of events required for the propagation of these failure modes were developed. The observations and insights acquired in this study were distilled into conclusions regarding the long-term performance of dams with seepage barriers.

The information derived from this study will be useful in 1) assessing the potential for internal erosion and piping developing in dams with seepage barriers, 2) designing to minimize that possibility, and 3) assessing the risks associated with these mechanisms of erosion and piping. It is envisioned that the results of this study will provide dam owners and engineers with a better understanding of the issues involved with dams having seepage barriers and that this understanding will lead to improved practices in assessing, designing, and monitoring of dam seepage barriers. In addition, by improving the means by which seepage barriers can be assessed and designed, it is hoped that the confidence level that dam engineers have with regard to properly designed seepage barriers will be increased, and that properly designed seepage barriers can be viewed as safe and viable alternatives for mitigation of seepage problems.

ACKNOWLEDGEMENTS

First, I would like to thank my advisor, Professor J. Michael Duncan, for his guidance and mentorship with this dissertation and during my doctoral studies. Professor Duncan's mentorship throughout my class work, research, and teaching has added tremendously to my academic experience. It has been an honor to work with Professor Duncan who is both a world-class scholar and a truly generous, honorable, and dedicated man.

I would also like to recognize the members of my committee: Professors Thomas L. Brandon, George M. Filz, Ronald D. Kriz, and James R. Martin. Their comments and input have added to the quality and completeness of this dissertation.

Funding for this project was provided by the U.S. Bureau of Reclamation, United States Society on Dams, and the Virginia Tech Center for Geotechnical Practice and Research. I am indebted to these organizations for their support, without which these studies would not have been possible.

Thanks also go to my parents for their long-distance support and especially their efforts to keep in touch with their grandchildren from across the country.

I would like to acknowledge my children, Logan, Meg, and Leah for putting up with the changes in their lives associated with my studies. They have moved across the country, away from family and friends, and have put up with Dad studying and writing during evenings and weekends.

Finally, and most importantly, I would like to thank my loving wife, Tanya, for her support throughout the three-and-one-half years of my doctoral studies. She has put up with moving away from family and friends, living on a tight budget, and many nights and weekends as a PhD widow. I am indebted to her for her support, understanding, and love throughout this endeavor.
